The bevellings to be taken for each futtock and top-timber are as follow: for the lower or first futtocks, lower diagonal *a*, second diagonal or floor-ribband *b*, third diagonal or first futtock-ribband *c*, and first futtock-head *d*, *Plate VII. fig. 7*. For second futtocks, floor-head, which is second futtock-heel, third diagonal or first futtock-ribband, first futtock-head, fourth diagonal or second futtock-ribband, and second futtock-head. For the third futtocks, first futtock-head, which is the third futtock-heel, fourth diagonal or second futtock-ribband, second futtock-head, fifth diagonal or third futtock-ribband, and third futtock-head. For the fourth futtocks, second futtock-head, which is fourth futtock-heel, fifth diagonal or third futtock-ribband, third futtock-head, main-breadth, port-fill-line, top-timber-line, and top-side. For the top-timbers, third futtock-head, which is the top-timber-heel, main-breadth, port-fill-line, top-timber-line, and top-side. The bevellings for the main-breadth, and all above, may be taken from the half-breadth plan, by fixing the stock of the bevel to the joint of the timber, and moving the tongue to the respective half-breadth lines.

It is necessary, in the practical application of the moulds, to have the size of the timbers the moulding-way; this must be either set off on the bevelling-boards, or on the moulds. As the latter may be reckoned the best way, first set off the scantling of the timbers the moulding-way at every head, &c. at dead-flat; thus, at the top of the sides, 6 inches, *Plate VII. fig. 3*; at the upper deck ports, N,  $10\frac{1}{2}$  inches; at the gun-deck ports, M,  $11\frac{1}{2}$  inches; at the third futtock-heads, I,  $11\frac{3}{4}$ ; at the second futtock-heads, G,  $12\frac{1}{2}$  inches; at the first

first futtock-heads, E, 13 inches; and at the floor-heads, C, 13 $\frac{3}{4}$ . Then pinning a batten to all those spots, making it fair to the cutting-down of dead-flat at the middle line, will give the scantling-line, or inner edge of timber dead-flat; then take the size or moulding at the head or heel of every timber, and set off on their respective moulds.

Then to mould the floors, the mould is laid on the timber, and the moulding edge of the intended floor is brought towards the outside of the piece; then see if there is cutting-down in the piece sufficient for bevelling, and substance below it for seating, which should be no less than sixteen inches, increasing forward and aft, as the strength may require. When that is done, if there remains sufficient wood to mould the floor agreeably to its line on the mould, which is readily seen by marking spots on the piece corresponding with the lines on the battens, and thence observing whether there is wood sufficient to mould the inside agreeably to the scantlings marked on the mould. The above-mentioned spots may be made conspicuous on the piece, and the cutting-down also marked from the mould; then its corresponding first futtock-mould will finish its moulding edge, or a pliable batten may be pinned to the spots, and the moulding edge formed as low as the piece will admit (so that it is not within the given substance below the cutting-down), the batten being fair rased by its edge; then rase up the firmarks for the diagonals to apply the bevellings. Set off on a square from the outside the given scantlings, and pin the batten thereto, as also to the cutting-down, and rase by the edge; the inside of the floor will then be completed, and the deficiency, if any, below the seating is made good by chocks.

To mould all the futtocks except the fourth, the mould need only be laid off to the outer edge of the piece; and if the piece comes near enough to the mould to allow for the scantlings and bevellings outside and inside, rase by the edge of the mould likewise the firmarks, head, and heel; then from the moulding edge set off the scantlings square from their respective places, and try if the edge of the mould will not form the inside by moving up or down; if not, it must be finished by a pliable batten, as before directed. Observe, should any of the timbers be a few inches short in the length, let them be made good by the next timber upon it, as through chocks are not to be admitted.

The fourth futtock-moulds are laid upon the piece, and should be in an horizontal position (as indeed all moulds should to try the bevellings); then see that the piece forms agreeably to the line on the mould of the timber intended to be moulded, by making a hole with a gimblet through the holes at the various firmarks belonging to the main-breadth; observing, at the same time, that the piece is strictly conformable to the head of the mould above. When both are found to agree, and there is wood in the piece sufficient for the bevellings, rase by the side of the mould inside and out as low as the main-breadth: below that it may be completed by the upper part of the corresponding third futtock-mould, keeping it well to the holes made by the gimblet at the heel and third futtock-ribband, which firmarks must be also rased up on the piece, likewise the heights of breadth, port-fill lines, top-timber line, and top-side. The inside towards the heel is finished by the scantlings given, and a batten as before described. But when fourth futtock-moulds have spilings at their heads, owing to the difference in the tumbling-home of the side, then, as the mould lies upon the piece, and the heel is found to answer, it must be seen that the upper part of the piece answers to the spiling marked upon the mould; then, towards the heel may be finished as be-

fore; but the upper part above the upper-breadth sweep must be completed by a mould made to the top-timber hollow. The top-timber line marked thereon must be placed to that given by the fourth futtock-mould, with its edge there fixed to the spiling, and its heel to the back of the upper-breadth sweep; its edge may be then rased by, and the fourth futtock will be formed up to the head or top of the side from the moulding-edge; then set off the scantling at the different firmarks, and the top-timber hollow placed to those spots will form the inner edge of the said fourth futtock, and so will the timber be completed.

Top-timbers are moulded so much like the fourth futtocks, as to render a further description unnecessary.

The moulds for the stem, stern-post, &c. The mould for the stem is made to the lines representing the fore and after sides, or moulded breadth, from the head to the heel; but in pieces, according to the number the stem is to be composed of. The rabbet is described on the mould, or represented by the batten that forms the aft-side being made parallel to the thickness of the bottom plank; but if the rabbet comes in the middle, a batten of this description must be nailed on the mould, agreeably to the rabbet in *Plate VII*. Upon this mould must be marked the heights of all the decks, likewise of the harpins and cheeks, by an horizontal line at each height across the mould. Some mark every two feet above the upper edge of the rabbet of the keel upon this mould. There should be a perpendicular line, or, in other words, a square line to set the stem by, which may be the perpendicular of the gun-deck.

The stern-post mould is made to the lines representing the fore and after sides of the stern-post, from the head to the heel, and a batten to the rabbet; then, across the mould may be marked the height of the upper side of the wing, filling, and deck-transoms at the middle line, also the heights of the harpins. Another mould is also made for the bearding-line on the post, the aft-side of which must be fayed to the bearding-line from the upper side of the wing-transom down to where the bearding-line intersects the fore-side of the inner post, and the fore-side of the mould to the fore-side of the inner post; then upon the mould must be marked the stations of the upper sides of all the transoms, marking their respective names thereon. By many, the use of this mould is superseded by marking the whole of the heights, &c. upon the stern-post mould.

Another mould may be made to the thwartship bearding of the stern-post, thus: square down the intersection of each water-line, with the fore side of the inner post in the sheer-plan, to its corresponding water-line in the half-breadth plan; then take the several half-breadths from the middle line in the half-breadth plan, and set them off from a straight line at their corresponding heights in the sheer-plan; and a curve made to pass through those spots will be the thwartship bearding of the post, at the fore-side of the inner post, from the middle line, to which the mould is to be made; the same may be done, and a mould made to the fore-side of the stern-post.

A mould should be made to the dead-wood abaft, which is limited on the upper part by the cutting-down line, on the lower part by the upper edge of the keel, the after end by the fore-side of the inner post, and the foremost end by the aft-side of the after-floor. The mould for the dead-wood knee is represented on it; and so likewise are the several pieces that compose the whole, as they can be gotten to as to give shift to each other. Upon this mould are fastened battens, with one edge straight to the middle line: they correspond with the stations of the square timbers; and the other edge

is hollowed to the moulding of the timbers, which gives the half-thickness of the dead-wood below the stepping or bearding-line, as marked on the mould, as all above that line the dead-wood is trimmed perpendicular to the siding of the keelson. To make this mould more conveniently, it may be made in two parts, separating lengthways at about half its depth.

*To Lay-off the Cant-timbers, Plate VII. Laying-off, Plate A.*

The necessity and utility of canting the timbers forward and aft, have been already explained in constructing of the sheer-draught, *Plate I.* But that the reader may have as clear an idea as possible of the design of the cant-timbers, and their disposition when canted, observe then in the half-breadth plan, *Plate VII. fig. 4,* where the lines representing the joints of the cant-timbers, as transferred from the sheer-draught, *Plate I.,* intersect the middle line, there may be supposed the hinge of a door; and the lines for the cant-timbers may be supposed to represent the door, which may be swung forward at pleasure; so that if the ship was on an even keel, the sides of the cant-timbers (though trimmed to their proper form) would become perpendicular, similar to the door; or supposing the form of the cant-timber was drawn on the door and sawed out, it would be perpendicular as before. The diagonal ribbands are similar to the cant-timbers in this respect: and as the cant-timbers at the middle line become perpendicular, making one straight section in the direction of the cant-timbers; so the cant-ribbands at their intersection of the middle line in the body-plan, *fig. 3,* become horizontal, that is, parallel to the keel at the middle line all fore and aft, provided that the ribbands for the fore and after bodies meet at the middle line, as the floor-ribbands do in *fig. 3.* Or otherwise, as the cant-timbers are represented by a door that is hung perpendicular, so may the cant-ribbands be represented by any plain surface, like the flap of a table, that may be hung horizontal to the side of a room; then will the side of the room become the middle line of the ship, equal to the middle line in the half-breadth plan, *fig. 2,* and the flap of the table may be canted down to the direction of the diagonal lines in the body-plan, *fig. 3.* To understand it clearly, suppose the edge of the flap of the table to be cut in the form of one of the diagonal ribbands laid off in the half-breadth plan, *fig. 2;* let it be the floor-ribband: then within the floor-cant-ribband in the half-breadth plan, *fig. 4,* is the square or horizontal ribband B, which is the form or distance from the middle line which the flap of the table makes when canted down, as in *fig. 3.* The cant-ribband in the half-breadth plan, *fig. 4,* is the same as the flap of the table, if lifted up till its level, shewing the extreme half-breadth of the ship, were it cut in the direction of the cant-line in the body-plan, *fig. 3.* The cant-ribband in the half-breadth plan, *fig. 4,* is the proper line to make the mould to for the harpin. But the intersection of the cant-timbers in *fig. 4,* with the cant-ribband, is not the proper station of the timbers; because the cant-ribband is now raised from its proper place, and the timbers remain as before. Therefore, where the cant-timbers cross the square ribbands, square them up to their corresponding cant-ribbands, as may be readily seen in *fig. 4,* which are the proper stations of the cant-timbers on the harpin-moulds. For if the flap of the table, which is the cant-ribband-line, and hinged at the middle line, was to fall down in its proper place, it would then be exactly underneath the long ticked line B, which is the square ribband. The stations of the square timbers on the harpin-mould will make no alteration, because the mould falls in the direction of the square timbers. Strike a straight line from the intersection

of the cant-timber with the middle line, to their corresponding stations on the harpin-mould; as at cant-timber S, *fig. 4.* This will give the direction as the cant-timbers stand on the harpin-mould.

Before we proceed any further in laying-off the cant-timbers, the fore cant-body, that is *figs. 3* and *4,* should be proved by the square timbers and water-lines, as far aft as timber M at least; for it is possible that the ribband-lines may have a fair appearance on the floor, and yet not produce a fair body in the ship; but if the water-lines and ribband-lines agree, there need be no fear of producing a fair bow, as the lines cannot be altered after the cant-timbers are laid off.

Therefore, transfer the water-lines from the body-plan, *Plate I.,* to the body-plan on the floor, and then they may be all run from timber M, and ended forward, as directed in the constructing the sheer-draught, *Plate I.* These lines laying with a more acute angle with the timbers, any unfairness in the body is more readily seen; but when the ribband-lines and water-lines produce fair curves in *fig. 4,* and likewise fair timbers in *fig. 3,* we may proceed to lay-off the square ribband-lines, which may be done in the following manner: mark on the edge of a batten the distances taken square from the middle line of the fore body-plan, *fig. 3,* to where the floor-ribband intersects each of the square timbers O, Q, S, U, X and Y. Then set them off from the middle line on their corresponding timbers in the half-breadth plan, *fig. 4.* The ending of it may be performed as the ending of its corresponding diagonal or cant-line, with only this difference, that, instead of taking the half-breadth of the stem in the direction of the diagonal line, it must be taken square from the middle line in the body-plan, *fig. 3,* to where the floor-ribband intersects the half-breadth of the stem. Then, by pinning a batten to the spots on the timbers and to the ending, is produced the curve B, or square ribband No. 2, marked on the floor S 2, and its corresponding ribband C 2, meaning square 2 and cant 2, which have a multiplicity of words; and it may be understood more clearly as we proceed, than by expressing the ribbands by their proper names, as floor-ribband, &c. Then, by proceeding in the same way with the rest of the diagonal or cant and square ribband-lines, they may be all described on the floor, as at A 1, B 2, C 3, D 4, and E 5, *Plate VII., fig. 4.*

Now proceed to the operation, where the cant-timbers in *fig. 4.* intersect the square ribbands A, B, C, D, and E, or 1, 2, 3, 4, and 5. Take the nearest distance or square from the middle line, and set them off square from the middle line to intersect their corresponding ribbands in the body-plan, *fig. 3,* and from thence level out lines at pleasure, as may be seen in *fig. 3.* Then take the distance from the middle line in *fig. 4,* in the direction of the cant-timbers, to the intersections of the square ribband with the cant-timbers, and carry them to their corresponding timbers in the body-plan, *fig. 3,* setting them off square from the middle line on the lines before levelled out. This will give the spots for the timbers, and likewise the proper stations of the harpins to be crossed on the timbers.

Square up from the half-breadth plan, *fig. 4,* where the cant-timbers cross the half-thickness of the dead-wood H, to the bearding-line R in the sheer-plan. Likewise from *fig. 4,* where the cant-timbers cross the main half-breadth line, port-fill line, top-timber half-breadth, and half-breadth at top-side, let them be squared to their corresponding lines in the sheer-plan.

Take the heights in the sheer-plan, where the cant-timbers cross the bearding-line, likewise the lower and upper main-breadths,

breadths, the port-fill line, the top timber-line, and top of the side, and set them in up the body-plan, *fig. 3*, striking lines thereto parallel to the base line; then take the distance from the middle line in the half-breadth plan, *fig. 4*, in the direction of the cant-timbers, to the line for the half-breadth of the dead-wood at each timber, and set them off from the middle line in the body-plan, *fig. 3*, on the heights set up for the bearding. This will give the ending of the cant-timbers on the bearding-line.

Take the distance from the middle line in the half-breadth plan, *fig. 4*, in the direction of the cant-timbers, to the main half-breadth, port-fill half-breadth, top-breadth, and top-side, and set them off in the body-plan, *fig. 3*, square from the middle line, on their corresponding heights. This will give the spots through which the curves of the timbers are to pass by pinning a batten, and likewise the proper heights of the harpins on the timbers.

#### *To Lay off the Bevellings of the Cant-Timbers.*

Let the bevelling of cant-timber *u* be required, and this will suffice for all, as the process is alike. Strike a line afore and likewise abaft the joint of cant *u*, in the half-breadth plan, *fig. 4*, to the scantling of the timber, which should be the breadth of the bevelling-board. Square a line from the intersection of the joint with the middle line, to cross the edges or siding of the timber *u* in the half-breadth plan, as at *L*, *fig. 4*; then take the nearest distance or square to the middle line, from where the ticked line afore *u* crosses the square ribbands *A*, *B*, *C*, &c. and set it off square from the middle line in the body-plan, *fig. 3*, on each corresponding ribband, in the same manner as was done for the joint of the timber, and level them out on each side of the diagonal ribbands, because the distance taken off in the direction of the bevelling edge in *fig. 4*, will sometimes be without and sometimes within the diagonal. Then take the distance from the square line, which crosses the middle line at the joint in *fig. 4*, to the square ribbands *A*, *B*, *C*, &c. in the direction of the ticked line, before the joint or fore edge of *u*, and set them off square from the middle line in the body-plan, *fig. 3*, on their corresponding spots before levelled out. Where the same ticked line, in *fig. 4*, intersects the half-breadth of the dead-wood, square it up to the bearding-line in the sheer-plan, and transfer that height to the body-plan, *fig. 3*. Then take the distance in *fig. 4*, from the squared line, as before, to the line for the half-breadth of the dead-wood, in the direction of the ticked line; and set it off square from the middle line in the body-plan, *fig. 3*, on the height of the bearding-line, which gives a spot to finish the lower end. Where the same ticked line, in *fig. 4*, intersects the main half-breadth line, square it up to the lower height of breadth line in the sheer-plan, and transfer that height to the body-plan, *fig. 3*. Then take the distance in *fig. 4*, from the square line, as before, to the main half-breadth, in the direction of the ticked line, and set it off square from the middle line in the body-plan, *fig. 3*, on the height last set up. Then, by pinning a batten through those spots, the fore edge is produced in the body-plan from the heel to the lower height of breadth.

Proceed exactly the same with the edge abaft the joint of *u*, and the two edges will be run in the body-plan, *fig. 3*, as the ticked lines there represent, the nearest distance of which, taken with compasses, to the joint at every ribband, shows how much bevelling the timber requires at each place in the breadth of the bevelling-board; that is, if the ticked line, which is the bevelling edge of the timber, come within the joint of the timber (or nearer the middle line), then the bevelling of the timber would be so much within (or under

from) a square, consequently the ticked line without the joint will be so much without (or standing from) a square.

*Figs. 5* and *6*, exhibit the form of the fashion-piece and cant-timbers of the after-body, which being laid off and bevelled in the same manner as cant-timber *u* in the fore-body, it is useless to explain them; nevertheless, cant-timber *35* is completely laid off, that it may be referred to at leisure. It may be necessary to add, that the greatest pains are required to prove the correctness of the after-body, not only by the water-lines, but by the vertical sections or buttock-lines, and by introducing one or more square timbers abaft *36*, to prove the buttock quite aft, and hence called proof-timbers. When these are all found to agree, it will not only produce a fair cant-body, but likewise a fair stern-frame. See *Plate IX. Laying-off C.*

Observe, the diagonal *H*, *fig. 5*, or third futtock-ribband, ends upon the aft-side of the wing-transom, which requires the following method to end it. Transfer the height from the line *AA*, or upper edge of the keel, where the diagonal *H* intersects the margin-line of the transom in the body-plan, *fig. 5*, to cross the margin-line in the sheer-plan; and where it crosses, square it down to the margin-line in the half-breadth-plan, *fig. 6*; then take the distance from the middle line in the body-plan, *fig. 5*, in the direction of the diagonal *H*, to where it intersects the margin-line of the wing-transom, and set it off from the middle line in the half-breadth-plan, *fig. 6*, on the line squared down from the margin-line, which ends the diagonal *H*, or third futtock-ribband. To end it as a square ribband, take the nearest distance, or square, from the middle line in the body-plan, *fig. 5*, to where the diagonal *H* intersects the margin-line, and set it off square from the middle line, *fig. 6*, to intersect the margin-line there; and if truly squared down for ending the cant-ribband, the ending of the square ribband will also intersect the margin-line at the same place in *fig. 6*.

*Moulds* are generally made to each timber, or futtock, in the cant-bodies; and in crossing or marking them, it must be observed, that the stations of the heads and ribbands are where the lines levelled out intersect the lines of the cant-timbers. On the heels of the double futtock and half-timber moulds, nail on a batten to the stepping and side of the dead-wood, by which the heel is to be cut off. To perform this, set off on the half-breadth plan, *fig. 6*, the thickness of the stepping, or dead-wood, above the stepping-line, which may be the half-thickness of the keelson, from and parallel to the middle line, as there ticked; then from the middle line in the half-breadth plan, *fig. 6*, take the distance in the direction of the cant-line to the ticked line, and set it off in the middle line in the body-plan upon the line levelled out for the heel of the same cant-timber; and from that spot square up a line to the upper side of the cutting-down, which will give the height of the inside of the timber, and will represent the side of the dead-wood to which the batten is to be nailed. A firmark, crossed on this batten at any certain height above the keel, and carefully crossed on the side of the timber, when trimmed to correspond to a line gotten upon the dead-wood at that same height above the keel, will be the surest and best method of keeping the cant-timbers to their exact height on the ship.

*Bevellings.*—To take the bevellings, provide a board as broad as the scantling of the timber, and long enough to take all the bevellings of the fore-side of the joint, and likewise abaft it, as *Plate VII. fig. 9*. Begin with the fore-side of cant-timber *u*, *fig. 4*: the heel-bevelling is the first to be taken, which gives the direction to trim the heel of

## SHIP-BUILDING.

the futtock the fore and aft-way, or faying to the dead-wood; therefore, the outside of the dead-wood being parallel to the middle line, apply the stock of a bevel in the direction of the joint of cant-timber *u* in the half-breadth plan, and place the tongue well with the middle line, or at the half-thickness of the dead-wood, as at *F*, *fig. 4*, letting the tongue teach forward, which will be an under-bevelling, and may be thence marked on the board. The bevelling of the heel, to trim it to the stepping or bearding-line, is next taken. Thus, where the joint of cant-timber *u* intersects the half-thickness of the dead-wood, in *fig. 4*, square it up to cross the bearding-line in the sheer-plan; and, at that place, let the tongue of the bevel be placed to the bearding-line, teaching forward, and move the stock till it is perpendicular, as at *O* in the sheer-plan, which will give the above bevelling, which may be the next marked on the board.

The outside bevelling of the heel is best obtained by trimming the heel parallel to the inside, where it fays to the side of the dead-wood, to the thickness of the stepping. Then, to take the bevelling at the lower diagonal, fix one leg of a pair of compasses in the line of the cant-timber *u*, in the body-plan, *fig. 3*, where the level line intersects, and extend the other leg to the ticked line, representing the fore edge of the timber *u*, sweeping it till you get the nearest distance, and that will shew how much the bevelling is within or without a square in the breadth of the bevelling-board; if the former, the ticked line must be towards the middle line of the joint, and of course the latter without it; then do the same with the diagonal lines, and the bevellings of each, so taken, may be marked on the board.

To take the bevellings at the main and top-breadths, and at the port-fill line between them, apply the stock of the bevel to the joint of the cant-timber *u*, in the half-breadth plan, *fig. 4*, as at *G*, and place the tongue in the direction of the respective half-breadth lines, as at top-breadth, observing to let the tongue teach forward: these bevellings are set off on the board, as taken, and the whole kept at a regular distance of about three-quarters of an inch on the left-hand side of the board; and, to complete them, mark their respective names and fore-side of cant *u*, as *a*, *fig. 9*.

The bevellings may now be taken for the aft-side of cant *u*; but the operation is performed like the former, only observing that the square line at the heel comes within side of the middle line of the half-breadth plan, and likewise when the bevel is applied to take the bevellings at main-breadth and above, the tongue of it must teach aft; these bevellings may then be marked on the same side of the board below the others, and the board for cant-timber *u* will be complete, as *b*, *Plate VII. fig. 9*.

In like manner may the bevellings be taken for cant-timber *35* at the aft-side, and marked on another board, as *a*, *fig. 10*; likewise for the fore-side, as *b*, *fig. 10*; and so on for all the other cant-timbers, both on the fore and after cant-bodies, and also for the fashion-pieces, and marked on their respective boards.

*Making the Moulds, and taking the Bevellings of the Harpins,*  
*Plate VII. Laying-off, Plate A.*

The ribbands to which the harpins are connected reach along the ship fore and aft; but in the wake of the cant-bodies, or at the fore and aft parts of the ship, they are termed harpins, and are trimmed to the shape of the ship's body by moulds and bevellings from the mould-loft. The reader, in the foregoing section, being made acquainted with the nature of canting the ribbands, it may only be necessary to observe, that the ribbands at the port-fill line

would be placed better about eight inches below the upper side of the lower fill, so that they may be let out above the ribband; and likewise the ribband at the top timber-line should be so placed, that one of the sheer-strakes should be wrought before it is disturbed. This is commonly a larger ribband, like that at the floor-head, to keep the top-side fair.

The harpin-moulds are made of fir-board, to the diagonal or cant-ribband lines in the cant-bodies, *figs. 4* and *6*; from the stem or stern-post, to the adjoining square timber, as *O* and *28*, to be about seven inches broad; and as they lie in their places on the floor, mark the stations of the cant-timbers upon them thus. Where the cant-timbers intersect the square ribbands, square them up to their corresponding cant-ribbands; then striking a straight line from the intersection of each cant-timber, at the middle line of the half-breadth plan, to the corresponding stations last squared up, will give the direction of the cant-timbers as they stand with the harpin-mould, as at cant-timber *s*, *fig. 4*. The method of taking the bevellings is at every square timber, which must be likewise marked on the harpin-mould before it is displaced. The stations of the square timbers make no alterations, because the harpin is lowered to its cant in a perpendicular direction. Fix the stock of a bevel in the direction of the diagonal, say the upper one, or third futtock-ribband *H*, in the body-plan, *fig. 3*, and the tongue against the outside of the square timber *O*; then mark it on a board (the board to be as broad as the harpin is deep or sided), and so on with the other square timbers before *O*, marking each of them, and its respective timber, as before; then fix the stock of the bevel upon the same harpin-line in the body-plan, *fig. 3*, and the tongue against the side of the stem, and mark that likewise upon the board; and by that bevelling the foremost end of the harpin must be trimmed, to fay against the stem. The fore and aft part of the harpin against the stem is obtained by the foot, or swell on the fore-end of the harpin-mould, which is cut off well with the half-thickness of the stem, taken diagonally, and parallel to the middle line, in the half-breadth plan, *fig. 4*. Another bevelling is taken and applied over the end, after it is cut off to the fore and aft-line, and bevelled against the stem, thus; fix the stock of a bevel upon the horizontal line of the harpin upon the stem, and teach the tongue down the aft-side of the rabbet; then mark it on the board, and the bevellings are completed. To complete the harpin-mould, square down from the sheer-plan, where the fore-side of the rabbet of the stem crosses the upper side of the harpin, to the mould on the half-breadth plan, and make a firmmark, which being kept to the fore-side of the rabbet of the stem on the ship, is the guide to fix the harpin to.

*To Lay-off the Hawse-Pieces, Plate VIII. Laying-off B.*

This plate represents the lines on the floor, as before observed, but made separate here for clearness. The hawse-pieces, in *figs. 1* and *2*, are supposed to stand perpendicular when in their places, and their sides to look fore and aft. They may be called square timbers, only they look fore and aft, instead of athwartships. This being the first method of laying-off the hawse-pieces, will be easiest understood.

Strike in straight lines as much asunder, and parallel to the middle line in the half-breadth plan, *fig. 3*, as the knight-head and hawse-pieces are to be sided, marking them *K, H, 1, 2, 3, and 4*.

Where the edges of the foremost cant-timbers, marked *E F* in the half-breadth plan, *fig. 3*, cross the water-lines,  
main-

main-breadth, and level line, at their heads A, square them up parallel to any of the square timbers, to their corresponding lines in the sheer-plan, *fig. 1*, and likewise do the same with the bearding-line, which will give the ending of the timbers on the bearding-line; then, by pinning a batten to all those spots, this shews the thwartship view of those cant-timbers when in their places, as F G.

Where the lines for the knight-head and hawse-pieces, in the half-breadth plan, *fig. 3*, cross the water-lines, main-breadth, and heads, let them be likewise squared up to their corresponding lines in the sheer-plan, *fig. 1*; a batten pinned to those spots, making a fair line, and the edge rasped or chalked by, gives the form of the knight-head and hawse-pieces, and shews them in their proper places; and where the lines for the knight-head, and 1, 2, and 3 hawse-pieces, meet the fore-side of the short cant-timber, before cant *y*, in the half-breadth plan F, *fig. 3*, let them be squared up to the fore-edge, G, of the same timber, in the sheer-plan, *fig. 1*; likewise the heel of hawse-piece 4 crossing the fore-edge of cant *y*, which gives the heeling of the knight-head and hawse-pieces.

The midship side of the knight-head connecting well with the side of the stem, the rabbet being in the middle of it, makes the aft-side of the rabbet the fore-side of the knight-head. But when the rabbet is not in the middle of the stem, it connects well with the side of the apron and dead-wood, consequently the bearding-line represents the fore-side.

Before the moulds for the knight-head and hawse-pieces can be crossed, if made, the hanging of the harpins must be described in the sheer-plan, *fig. 1*. Thus, take their heights perpendicularly from the base line, where they intersect the square timbers, and at the side of the stem, in the body-plan, *fig. 2*, and transfer them respectively to the sheer-plan, *fig. 1*; then, by pinning a batten to those heights, we have the lines A, B, C, D, and E, or hanging of the harpins in the sheer-plan, *fig. 1*.

The heels of the knight-head and hawse-pieces, where they intersect the cant-timber in the sheer-plan, *fig. 1*, are lined up perpendicular, in which direction they must be cut off, to lay against the side of the cant-timbers F and G.

The moulds may now be made of inch-board to the lines marked K, or knight-head, and 1, 2, 3, and 4 hawse-pieces in the sheer-plan, *fig. 1*, from the heads to the heels, and the moulds at the heels to be cut off in the direction of the perpendicular line thereat, and while in their places mark a firmark on the moulds, wherever the harpins intersect the moulding edge of the knight-head and hawse-pieces, also the main-breadth and head, and as many between as it may be thought necessary to apply bevellings, as may be seen at the hawse-piece 4. The firmarks at the harpins also shew the height to keep the harpins on the ship.

The bevellings may be next taken, and marked on a board, which should be as broad as the siding of the hawse-piece, having a board to the knight-head, and each hawse-piece, or all on one board, if not thought unbandy, as *fig. 4*. The first bevelling taken from the knight-head or hawse-pieces to the side of the cant-timber in the half-breadth plan, *fig. 3*, as G for the knight-head, and H for the hawse-piece 4, is the under bevelling. To cut off the heels to lay against the cant-timber athwartships, the bevel should be applied square from the heel, as cut off, to the perpendicular lines at the heels in the sheer-plan, *fig. 1*. But to get the bevelling at the heel to counter-mould them, when the heel is cut off and trimmed to the above bevelling, the foremost edge of cant *y* must be laid off on the square, as *i*, and on the cant, as *b*, in the body-plan, *fig. 2*, as the joint of any of the cant-

timbers were in *Plate VII.*; and so must likewise the fore edge of the cant-siding before *y*, the latter being introduced only to shorten the heel of the knight-head and foremost hawse-pieces. Then strike in the body-plan, *fig. 2*, the siding of the knight-head and hawse-pieces parallel to the middle line; and where the moulding edge at the heel intersects the square edge, or fore and aft view of the cant-timber, as *i* in the body-plan, *fig. 2*, level it out to intersect the cant edge *b*. To do this with less trouble, take the height in the sheer-plan, *fig. 1*, of the heels of the knight-head and hawse-pieces at their intersection of the thwartship view of the fore edge of the cant-timbers, as F and G, and set them up in the body-plan, on their respective cant edges, marking them up perpendicular; then place the stock of the level against the perpendicular lines, and the tongue to the cant edge of the timber, as G for the knight-head, and F for hawse-piece 4, which will give the exact bevelling to be applied on the heel when cut off for the counter-moulding of the knight-head or hawse-pieces.

The side of the knight-head and hawse-pieces being parallel to each other, they will serve, in the sheer-plan, *fig. 1*, for the bevellings of each other, similar to parallel lines laid down for the cant-timbers; for, as much as the moulding edge of the hawse-piece, 1, is within or abaft the moulding edge of the knight-head, from the head to the heel, so much is the bevelling of the knight-head within or under from a square, in the distance between the knight-head and the hawse-piece, 1, in the half-breadth plan, *fig. 3*; therefore with compasses sweep the nearest distance at each harpin, &c. from the moulding edge to the after edge of the knight-head and each hawse-piece, as may be seen at hawse-piece 4, in the sheer-plan, *fig. 1*, and set it within a square upon the board, as at *e*, *fig. 4*; and so on for the others.

The bevellings of the knight-head and hawse-pieces, if taken from the water-lines, main-breadth, &c. in the half-breadth plan, *fig. 3*, would be found to alter but little; yet they are not so true in their application as when taken on a square.

But was the counter-moulding bevelling at the heel correctly set off, and another at the head for the knight-head, then the mould for hawse-piece 1, being kept well at the head and heel, and to its proper height, must consequently counter-mould the knight-head exactly, if the knight-head could be gotten long enough to reach to the heel, or if the chock was fayed before it was moulded, and the knight-head properly sided.

In the same manner, the mould that is made to the moulding edge of the hawse-piece 2, would counter-mould the hawse-piece 1, and so on of the rest.

There is no necessity to run the water-lines in the half-breadth plan, *fig. 3*, on purpose to lay off the hawse-pieces, because there is a sufficient number of square harpins already run; for in the half-breadth plan, *fig. 3*, where the knight-head and hawse-pieces cross the square harpins, let them be squared up to their corresponding harpins in the sheer-plan, *fig. 1*, which will give the exact form of the knight-head and hawse-pieces; and, if the work is correct, will agree with the former by the water-lines.

*To Lay off the Hawse-Pieces, where the Sides are required to look fore and aft, and likewise to be sided less at the Heels.*

Every timber in the ship which is sided straight, must appear, either in plan or elevation, as one straight line; therefore it is necessary, before any operation can be performed, to have a clear idea of the disposition of the timber when in its place. The hawse-pieces are intended to look fore and aft, that is, at any particular height the sides of them

them are to be parallel to the middle line; but as the heels of them are to be sided less than the heads, they will consequently be nearer the middle line; therefore they will not appear in a straight line in the half-breadth plan, *fig. 7*, as they did in *fig. 3*, and cannot be viewed in a straight line, unless by supposing them really in their places in the body-plan, *fig. 6*.

Proceed to dispose of the knight-head and hawse-pieces as in the body-plan, *fig. 6*, where they will appear straight lines. The moulding edges are the thin lines, except the outside of hawse-piece 4, which is intended to be laid off, in order to get the bevellings of No. 4 hawse-piece.

The thwartship view of the foremost edge of cant-timber *y*, and the cant-filling before it in the half-breadth plan, *fig. 7*, which the knight-head and hawse-pieces end against, must be squared up and represented in the sheer-plan, *fig. 5*, as in the preceding operation.

The fore and aft view of the foremost edge of cant-timber *y*, and the cant-filling before it, both on the square and cant, must be laid off as *b, i*, in the body-plan, *fig. 6*, as before explained.

Now proceed to lay off the hawse-pieces, or to shew the form in which they will appear in the half-breadth plan, *fig. 7*. The knight-head is already laid off, because it is the same as the half-thickness of the stem in the half-breadth plan, *fig. 7*. Therefore take the distance square from the middle line to the heels of the hawse-pieces, where they intersect the fore and aft view of the cant-timbers *i* and *G* in the body-plan, *fig. 6*, and set them off square from the middle line in the half-breadth plan, *fig. 7*, on the edges of the cant-timbers *F* and *E*; which gives the heels of the hawse-pieces in *fig. 7*. Take the distance square from the middle line in the body-plan, *fig. 6*, to where the hawse-pieces cross the harpins, *A, B, C, D, and E*; and set them off square from the middle line, on their corresponding square harpins in the half-breadth plan, *fig. 7*. Likewise, in the same manner take the half-breadths in the body-plan, *fig. 6*, for the main breadth and the harpin at the head; and set them off in the same manner as before in the half-breadth plan, *fig. 7*. Then pin a batten to those spots, and mark the curves in the half-breadth plan, *fig. 7*, which shews the form they will appear in, were you right over them, and looking down upon them; occasioned by the different curves of the body when cut by these sections.

The next operation will shew the form of the body, supposing it to be cut by the different sections of the hawse-pieces, to which form the moulds are to be made to trim the hawse-pieces. Proceed in the following manner:

Where the hawse-pieces 1, 2, 3, and 4, in the half-breadth plan, *fig. 7*, cross the square harpins *c, d, e, f, and g*; and likewise the main-breadth *B*, and harpin above *A*; let them be squared up to their corresponding harpins in the sheer-plan, *fig. 5*, where they end against the edge of the cant-timbers *F* and *E* in the half-breadth plan, *fig. 7*: they may be likewise squared up to intersect the thwartship view *F* and *G* of those cant-timbers in the sheer-plan, *fig. 5*, to give the heels of the hawse-pieces. But this is not so true, as to take the heights of the heels where they intersect the fore and aft view of the cant-timbers *i* and *G*, in the body-plan, *fig. 6*, and transfer them to the sheer-plan, *fig. 5*, on the thwartship view of the said timbers *F* and *G*; this is the proper height of the heels; yet if both ways agree, it shews the truth of the work. Then pin a batten to those spots squared up, and mark the curves 1, 2, 3, and 4; this gives the moulding edges of the hawse-pieces, and shews them as they appear when in their places. This method is usually practised when required to be laid off in this manner,

and will suffice for practice; but by explaining the situation of those at present laid off, it will sufficiently shew they are not exact, therefore we shall point out a method the most accurate.

Consider the hawse-pieces as they are now laid off, and as they appear in the sheer-plan, *fig. 5*; you there see the exact form of them, supposing them to be in their places, and that you are looking level at them. You may therefore observe the exact form of the harpins, when you are looking level at them, where they appear at their proper heights: consequently, then, you have the exact length and form of the hawse-pieces only as they appear in a level view. And because they do not stand perpendicular, you cannot have the exact length nor form properly to mould them.

In order to shew the proper method that may be depended on, lay-off the moulding edge of hawse-piece 4, or the outside of No. 3, which will make the most difference, because it stands most from a perpendicular.

There must be supposed one given point to work from; therefore, it being the most proper, let it be the heel. Strike the level line from the heel in the body-plan, *fig. 6*, to the heel in the sheer-plan, *fig. 5*, as *f*. If the hawse-piece 4 was not laid off in the sheer-plan, *fig. 5*, the moulding edge must be gotten up, as before, from the half-breadth plan, *fig. 7*. Therefore, as it is, strike lines upwards, perpendicular from the separate harpins in the sheer-plan, *fig. 5*, where the moulding edge of hawse-piece 4 intersects them. Then take the distance from the heel of No. 4 hawse-piece, in the body-plan, *fig. 6*, to each harpin, main-breadth, &c. taken in the direction of the moulding edge of hawse-piece 4; and set them up perpendicular from the heel of hawse-piece 4, in the sheer-plan, *fig. 5*, on the lines before squared up, at their corresponding harpins: then pinning a batten to those spots, mark the curve in *fig. 5*, which will give the exact moulding of the hawse-piece, and the heights for the stations of the harpins to be crossed on the hawse-piece moulds.

Though the exact and proper method to lay-off the hawse-pieces is described by laying off No. 4, the explanation must suffice for this, being too minute to be drawn on the plate. Yet the first method is not entirely to be condemned, as they are shewn in the sheer-plan, *fig. 5*, because it makes so little difference in the moulding, that the error is not to be regarded in the practice. The greatest difference it makes is in the length, which, in No. 4, does not make it two inches longer. But the certainty of the latter method being the most correct, must be proved by working at extremes; that is, suppose the head of hawse-piece 4 to stand where it is in the body-plan, *fig. 6*, and the heel to be fixed at the middle line, then, if laid off by both methods, the difference would be readily seen, which method is best to be depended on.

The moulds for the knight-head and hawse-pieces are made to the lines in the sheer-plan, *fig. 5*, as before directed.

The bevellings, supposing the hawse-pieces to be properly laid off in the sheer-plan, *fig. 5*, are taken in the same manner as was shewn in *fig. 1*; for though they do not appear in the same manner in the half-breadth plan, *fig. 7*, yet in the sheer-plan, *fig. 5*, (their sides looking fore and aft,) you there see the form of them square from the plans of their separate sides: therefore the distance, as they appear from each other in the sheer-plan, *fig. 5*, at each harpin, is the proper bevelling of them, agreeable to their distance from each other taken at their corresponding harpins in the body-plan, *fig. 6*.

Where the heels of the hawse-pieces step on the thwartship view of the cant-timbers in the sheer-plan, *fig. 5*, line them

## SHIP-BUILDING.

them up perpendicular; which gives the disposition of the heels of the hawse-pieces to lay against the fore-side of each cant-timber.

The bevelling of the heels of the hawse-pieces must likewise be done the same as in *fig. 3*; for though in the half-breadth plan, *fig. 7*, the form of the moulding edges of the hawse-pieces appear in this view, yet the sides of them, at level heights, are exactly fore and aft; therefore the bevellings to trim the heels to lay against the side of the cant-timber, is the same for all the hawse-pieces, and must be taken with the stock of the bevel looking fore and aft, or parallel to the middle line, as is expressed by the bevel *G*, which is applied in the half-breadth plan, *fig. 7*, to take the bevelling of No. 4 hawse-piece.

To take the bevelling of the heel, to be applied when the heel is trimmed by the last bevelling, in order to counter-mould the hawse-pieces, transfer the heels of the hawse-pieces from the sheer-plan, *fig. 5*, to the cant-timber in the body-plan, *fig. 6*, as for taking the bevelling of the hawse-piece 4, and strike up a perpendicular line, to which apply the stock of the bevel, and the tongue to the fore cant-edge, as at *c*, *fig. 6*. This gives the bevelling of the heel, in order to counter-mould the hawse-pieces.

As the most accurate method of moulding the hawse-pieces has been treated of, it is requisite it should be so respecting the disposition of the heels, and the bevelling of the heels. As the bevelling of the heel is shewn for No. 4 hawse-piece, the following will explain the difference that may be expected, if the hawse-pieces were required to be laid off on extremes, or if a section of the body were required in such direction.

Set up any particular height on the hawse-piece 4, in the body-plan, *fig. 6*, and suppose it to be the height where the harpin *C* intersects it; then take that height from the heel of the hawse-piece No. 4, in the direction of the line of the hawse-piece, and set it up perpendicular from the heel of No. 4 hawse-piece, in the sheer-plan, *fig. 5*. Take the distance square from the middle line at the proposed height in the body-plan, *fig. 6*, and set it off square from the middle line in the half-breadth plan, *fig. 7*, on the cant edge *E*; there make a spot, and carry it square up to the ticked level line in the sheer-plan, *fig. 5*, and strike the line from thence to the heel of No. 4 hawse-piece, which gives the exact form of the heel to lay against the fore-side of cant-timber *y*.

From the spot before mentioned in the half-breadth plan, *fig. 7*, take the distance to the middle line in the direction of the cant-timber, as *E*, and set it off from the middle line in the body-plan, *fig. 6*, on the ticked level line, and draw it down to the heel of the timber; which is the proper line to which the stock of the bevel should be applied to take the bevelling of the heel, in order to counter-mould the hawse-pieces. The explanation of the above must suffice, as it would not only interfere with the method laid off, but also be too minute to be described on the plate.

Where the hawse-pieces in the half-breadth plan, *fig. 7*, cross the square harpins *c, d, e, f*, and *g*, square them up to their corresponding cant-harpins, as at *b*, which gives the proper stations of the hawse-pieces on the cant-harpins; but the direction of the hawse-pieces to be marked on the harpin-moulds will be fore and aft, as well on the cant-harpins as on those which lie level: such are the harpins at the port-sill and head; for where the hawse-pieces cross those harpins in the half-breadth plan, *fig. 7*, is the proper station of the hawse-pieces on the aforesaid harpins; or otherwise it is the proper distance from the middle line which the hawse-pieces will be on each harpin, when the harpins are

in their places; because those harpins are shewn in the half-breadth plan, *fig. 7*, as they really appear when they are in their places.

### *To Lay-off the Hawse-Pieces when canted.*

The method of laying off and disposing of the hawse-pieces when canted, is the most complete of any, as it is the best for the strength of the ship, and will likewise assist the conversion of the timber; for by canting them, they will not only be diminished at the heels, whereby a less piece of timber will make them, as in the foregoing method, but the bevellings will be less acute; and as the canting and diminishing of them at the heels are performed by one operation, they consequently must appear as straight lines when viewed in the half-breadth plan; and, as before observed, that all timbers, when canted nearer to a square with the body, add more to the security of the plank, and the timbers are not wounded so much by that security. The canting of the hawse-pieces is also some advantage to the hawse-holes; for although the hawse-holes are generally cut nearly parallel to the middle line, yet canting of them leaves most wood at the outside of the hawse-hole, which is the farthest from the middle line, as it is the wearing side of the hawse-hole.

Dispose of the hawse-pieces in the half-breadth plan as in *fig. 11*, on which plan they will be straight lines, similar to the cant-timbers. Strike in likewise the fore-side of the cant-timbers marked *E, F*, as before, against which the heels of the hawse-pieces are to be cut off.

Lay off the thwartship view of the hawse-pieces and fore-side of the above cant-timbers *E, F*, in the sheer-plan, *fig. 9*, in the following manner. Where the fore-side of the cant-timbers *E* and *F* in the half-breadth plan, *fig. 11*, crosses the half-thickness of the dead-wood *C*, square them up to the bearding-line in the sheer-plan, *fig. 9*, and in the same manner proceed at every water-line, 1, 2, 3, 4, 5, and 6; likewise with the main-breadth and harpin at the beak-head: then pin a batten to those spots, and mark the curves, as *F, G*, which gives the thwartship view of the fore-side of the cant-timbers the hawse-pieces heel against.

In the same manner proceed with the hawse-pieces: where, in the half-breadth plan, *fig. 11*, they intersect the water-lines, main-breadth, and harpin above, square them up to their corresponding lines in the sheer-plan, *fig. 9*; and where they intersect the fore-edges of cant-timbers *E* and *F* in the half-breadth plan, *fig. 11*, square them up to intersect the thwartship view of the said cant-timbers, as *F* and *G* in the sheer-plan, *fig. 9*. This shews the exact height of the heels of the hawse-pieces, where they step against the cant-timber, when they are in their places. Then by pinning a batten to all the spots squared up, mark the curves 1, 2, 3, and 4, which will give the exact thwartship view of the hawse-pieces, supposing they were in their places; but as the sides do not look fore and aft, these are not the proper lines to make the moulds to; but will be serviceable hereafter, to get the proper height of the harpins to be crossed upon the hawse-piece moulds. The moulding edge of the knight-head is the aft-side of the rabbet of the stem.

Where the knight-head and hawse-pieces intersect the fore-side of the cant-timber, marked *E* in the half-breadth plan, *fig. 11*, fit a batten in the direction of the line of the knight-head, or hawse-pieces; mark thereon the points where they are intersected by the water-lines; and set them off from the middle line in the body-plan, *fig. 10*, on their corresponding water-lines. Then take the heights, where the heels of the knight-head and hawse-pieces intersect the thwartship view of cant-timber *F* in the sheer-plan, *fig. 9*, and transfer them to the middle line in the body-plan, *fig. 10*.

Having

## SHIP-BUILDING.

Having the lower height of breadth and harpin at the beak-head laid off in the sheer-plan, *fig. 9*, take the heights where they intersect the thwartship view of the knight-head and hawfe-pieces, and transfer them to the body-plan, *fig. 10*. Then take the distances in the half-breadth plan, *fig. 11*, from the intersection of the knight-head and hawfe-pieces, with the cant-timber marked *E*, to the main-breadth and harpin at the beak-head, taken in the direction of the line, and set them off from the middle line in the body-plan, *fig. 10*, on their corresponding lines, marking spots. Then by pinning a batten to those spots, mark the curves *K, H, 1, 2, 3, and 4*, which are the proper moulding edges of the knight-head and hawfe-pieces, and consequently those to which the moulds are to be made. Now to give the direction for cutting off the heels to lay against the side of the cant-timber, the mould of No. 4 hawfe-piece must be cut off well with the middle line in the body-plan, *fig. 10*; but as the knight-head and the other hawfe-pieces cut off against the timber, before that which No. 4 heels against, take the height in the sheer-plan, *fig. 9*, where the heels of the knight-head, and *1, 2, 3* hawfe-pieces intersect the thwartship view of the foremost cant-timber at *G*, and transfer them to the body-plan, *fig. 10*; and where they intersect their respective hawfe-pieces, there strike up a perpendicular line, as at No. 3 hawfe-piece, which will also give the direction to cut off their heels against the said cant-timber.

But now, since they are laid off by the water-lines, the proper stations of the harpins below the main-breadth cannot be marked on the moulds. Therefore the level thwartship view of the harpins must be laid off in the sheer-plan, *fig. 9*, as before, which is the exact height of them when they are in their places; consequently, then, the points where they intersect the thwartship view of the knight-head and hawfe-pieces, shew the exact height to be transferred from the sheer-plan, *fig. 9*, to their corresponding lines in the body-plan, *fig. 10*, which gives the exact stations of the harpins to be crossed on the knight-head and hawfe-piece moulds.

The bevellings are to be taken thus: strike a line in the half-breadth plan, *fig. 11*, to the siding of the knight-head and hawfe-pieces, as was done for bevelling the cant-timbers, as the ticked line at No. 4 hawfe-piece, it being the clearest to be understood. Then square a line at the heel, where the moulding edge of No. 4 hawfe-piece crosses the cant-timber marked *E*. Then take the distance from the squared line in the direction of the siding or ticked line to the separate water-lines, where they intersect the ticked line, and set them off from the middle line in the body-plan, *fig. 10*, on their corresponding water-lines. Where the ticked line in the half-breadth plan, *fig. 11*, intersects the cant-line *E*, square it up to intersect the thwartship view *F*, in the sheer-plan, *fig. 9*, as marked with a star, and from thence transfer it to the body-plan, *fig. 10*, as far as the middle line. Then take the distance from the squared line at the heel in the half-breadth plan, *fig. 11*, to the cant-line *E*, in the direction of the ticked line, and set it off from the middle line in the body-plan, *fig. 10*, at the height last mentioned. Continue the ticked line or siding of the hawfe-piece to intersect the water-lines *1, 2, and 3*, in the half-breadth plan, *fig. 11*; then take the distance from the squared line at the heel to those water-lines in the direction of the siding or ticked line, and set them off from the middle line in the body-plan, *fig. 10*, on their corresponding water-lines to the left hand, which serves to prove the spot at the heel by continuing the bevelling edge to the lowest water-line. Where the ticked line or siding of the hawfe-piece *4*, in the half-breadth plan, *fig. 11*, intersects the main half-breadth and beak-head harpin, square them up to their corresponding lines in the sheer-plan, *fig. 9*, and trans-

fer them to the body-plan, *fig. 10*, striking level lines. Then take the distance from the squared line at the heel in the half-breadth plan, *fig. 11*, to the main half-breadth and beak-head harpin in the direction of the siding or ticked line, and set them off from the middle line in the body-plan, *fig. 10*, on their corresponding heights, which gives the spots to which a batten must be pinned, and the curve marked out thereby will be the bevelling edge of the hawfe-piece *4*; and at whatever distance the bevelling edge in the body-plan, *fig. 10*, is from the moulding edge of the hawfe-piece *4*, so much is the hawfe-piece under from a square in the distance from the siding or ticked line, to the joint of the hawfe-piece in the half-breadth plan, *fig. 11*.

The bevel *G*, as shewn in the half-breadth plan, *fig. 11*, gives the direction to cut off the heel. When the heel is cut off, in order to find the bevelling of the heel to counter-mould the hawfe-pieces, the fore-sides of the cant-timbers, as *E* and *F*, in the half-breadth plan, *fig. 11*, must be laid off in the body-plan, *fig. 10*, which may be done by the water-lines. Then transfer the height of the heel of the hawfe-piece No. 4, from the sheer-plan, *fig. 9*, where it cuts the thwartship view of the cant-timber marked *F*, to its corresponding cant-timber in the body-plan, *fig. 10*, and strike a perpendicular line; to which apply the stock of a bevel, and the tongue, to the cant-timbers, as at *M*; the same likewise for hawfe-piece No. 1, as at *L*, and so on for the others. This gives the exact bevelling to be applied when the heel is cut off, in order to counter-mould the hawfe-pieces, if it should be so required. The bevellings of No. 4 hawfe-piece are all taken at their heights, as may be seen in the body-plan, *fig. 10*, and marked on the bevelling-board, as at *a* in *fig. 12*: the laid heights to be all crossed upon the hawfe-piece mould.

### *To Lay-off the Hawfe-Pieces by the Square Harpins when canted.*

The square and cant-harpins being of necessity laid off in the half-breadth plan, *fig. 11*, it is necessary to explain the method of laying off the cant-hawfe-pieces by the square harpins, which are marked *e, d, e, f, g*, in the half-breadth plan, *fig. 11*. The point where the knight-head and hawfe-pieces intersect the fore-side of the cant-timber marked *E* in the half-breadth plan, *fig. 11*, is supposed to be in the middle line in the body-plan, *fig. 10*, which middle line will serve for laying off the knight-head and hawfe-pieces, as it did for the foregoing operation by the water-lines. By being laid off in the same body-plan, *fig. 10*, it will be a convincing proof that both methods may be depended upon, because they will be found to agree, as near as can be expected on so small a scale as the plate.

To explain the laying off the knight-head and all the hawfe-pieces would be too tedious; (though they are all laid off the same in the body-plan); for by laying off and bevelling the hawfe-piece No. 4, the ticked lines (which are transferred from the sheer-plan, *fig. 9*, to the body-plan, *fig. 10*, in order to give the proper stations of the harpins on the hawfe-piece moulds, when laid off by the water-lines) will now be proved to agree with the operation by the harpins.

Now the knight-head and hawfe-pieces are intended to be laid off together by the harpin-lines. There is no necessity to lay-off the thwartship view of them in the sheer-plan, *fig. 9*; but the thwartship view of the fore-side of the cant-timber they heel against will be wanted, to find the height of the heels. Having the level height of the harpins laid off before in the sheer-plan, *fig. 9*, where the fore-sides of the cant-timbers, marked *E, F*, intersect the square

square harpins *c, d, e, f, g*, in the half-breadth plan, *fig. 11*, square them up to their corresponding harpins in the sheer-plan, *fig. 9*. This gives the thwartship view of the cant-timbers; and if the work be true, it will answer the same as by the water-lines. The exact height of the heels should be found, in order to prove the rest of the work; and as the lines of the hawle-pieces in the half-breadth plan, *fig. 11*, are continued abaft the fore-side of the cant-timbers, as *E, F*, to intersect the square harpins *c, d, e*; then by having spots in the body-plan, *fig. 10*, beyond the middle line, (when the batten is continued to the spots beyond the middle line on those harpins,) it would intersect the middle line at the proper height of the heel of the hawle-piece.

To prove the hawle-piece No. 4, as laid off by the water-lines, let it be laid off by the level or square harpins: thus, where the moulding edge intersects the fore-edge of the cant-timber, marked *E* in the half-breadth plan, *fig. 11*, square it up to intersect the thwartship view *F*, in the sheer-plan, *fig. 9*; and transfer that height to the middle line in the body-plan, *fig. 10*. This gives the heel of the hawle-piece No. 4, exactly similar to the method by the water-lines.

Observe in the half-breadth plan, *fig. 11*, where the hawle-piece No. 4 crosses the square harpins, and from thence take the nearest distance to the middle line; and let them off on their respective harpins square from the middle line in the body-plan, *fig. 10*, there striking a level line, in the same manner as was done for the cant-timbers. Then take the distances in the half-breadth plan, *fig. 11*, from the intersection of the hawle-piece No. 4, with the cant-edge marked *E*, to where it intersects each of the square harpins, in the direction of the line for the said hawle-piece; and set them off square from the middle line in the body-plan, *fig. 10*, on their respective level lines before mentioned; observing to set off the distance to the left hand of those which were taken abaft the cant-line *E*. This gives the spots for the moulding edge of the hawle-piece No. 4; and is likewise the exact station of the harpins to be crosled on the moulds.

Proceed in the same manner to find the spots for the moulding edges of the other hawle-pieces; as those for the main-breadth and beak-head harpin are found in the very same manner as by the water-lines.

The *beveling-edge* is laid off in the very same way as the moulding edge; only the distance taken in the direction of the ticked or siding-line is taken from the squared line at the heel, instead of its intersection at the cant-edge *E*, in the half-breadth plan, *fig. 11*. The plate will shew that the difference of laying-off, between the water-lines and harpins, is in the performance only.

To find the proper stations of the knight-head and hawle-pieces on the harpin-moulds, we need only square up the intersections of them with the square harpins to the cant-harpins, in the same manner as was done for the cant-timbers. And the points where the knight-head and hawle-pieces in the half-breadth-plan, *fig. 11*, cross the harpins at the port-fills and beak-head, shew the proper stations of them, as they appear when the harpins are in their places, they lying level in a thwartship direction to the sheer of the ship, the fore and aft-way. The main breadth is only used as a beveling spot; for was it required to place a harpin to that height, its great sheer would require a very different operation to form the line to make the mould to.

To Lay-off the Transoms, Plate IX. Laying-off C.

The transoms and fashion-pieces compose the stern-frame. The upper ones are the wing, filling, and deck-transoms;

and there may be as many under the deck-transom as the form of the body will admit, of kindly growth. The uppermost is called the wing-transom, which is the base of the stern.

This may be admitted the strongest and best method of uniting the after-part of the ship together: the strongest, because every transom crossing the after-part of the ship, and bolting through the stern-post, they may be considered similar to the breast-hooks; so that when the planks are wrought on the buttock, and the wing-transom knees, and sleepers or diagonal knees are bolted, it may be allowed to be as strong as the fore-part or bow is with the breast-hooks, because the fore-part of the ship has no other assistance to keep the bows together.

As there are several operations required to lay-off the stern-frame, *Plate IX. Laying-off C*, is made a separate plate for that purpose; though it represents the lines on the floor, as before observed.

The fashion-pieces being struck in the half-breadth plan on the floor, and the water-lines run as in *Plate 1.*, square up the intersection of the fashion-pieces with the bearding-line, water-lines, the end of the wing-transom, and main half-breadth line in the half-breadth plan, to their corresponding bearding-line, water-lines, wing-transom, and height of breadth line in the sheer-plan; then a batten pinned to those spots will represent the thwartship view of the aft-sides of the fashion-pieces *T, F, P*, *Plate IX. fig. 1*.

Where the aft-sides of the fashion-pieces intersect the before-mentioned lines in the half-breadth plan, take the distances square from thence to the middle line; and set them off square from the middle line, on their corresponding lines in the body-plan. A batten pinned to these spots will give the fore and aft view of the fashion-pieces, generally called the square fashion-pieces, which are marked *S, F, P*, *Plate IX. fig. 2*.

Transfer from the sheer-plan of *Plate 1.* the heights of all the transoms to the sheer-plan on the floor; likewise the siding or depth of each transom, as *W, F, D, 1, 2, 3, 4, 5, and 6*, *Plate IX. fig. 1*.

In the body-plan, *fig. 2*, describe the upper side of the wing-transom *a*, by a segment of an arc to its round-up, till it intersects the aft-side of the foremost square fashion-piece *S*; and below that a parallel curve *b*, where the ends of the planks of the buttock are intended to be cut off, which is called the *margin-line*. Square down from the sheer-plan the aft-side of the wing-transom to the middle line of the half-breadth plan; and from thence describe the aft-side of the wing-transom at its upper side, by a segment of an arc to its round-aft, which shews the line to which the mould is to be made. Take the height of the margin-line *b*, at the middle line in the body-plan, *fig. 2*, and transfer it to the fore-part of the rabbet of the stern-post, in the sheer-plan, *fig. 1*; and from thence square it down to the middle line in the half-breadth plan, marking a parallel arc to the aft-side of the wing-transom, which is likewise called the margin-line. Continue to shew the level view of the moulding edges of all the transoms in the body-plan, *fig. 2*, in the following manner: the wing-transom and the filling under it lying level, they form the segment of an arc to their round-up, as above. This is the proper curve to which the round-up mould is made for siding those transoms. The next is the deck-transom, which is generally laid off to the round-up of the gun-deck beam; the other transoms below the deck lying straight and level, are represented by level lines only.

Transfer from *Plate 1.* the buttock-lines *1, 2, 3, 4, 5,* and

and let them be struck on the floor in the body-plan and half-breadth plan. Then proceed to run the buttock-lines in the sheer-plan, *fig. 1*, as directed in the construction of the sheer-draught, *Plate I*. The buttock-lines, the square timbers, and likewise the water and ribband-lines, should be made to agree to the greatest exactness.

The moulding edges of the other transoms may now be laid off from the buttock-lines in the sheer-plan, *fig. 1*; but if they are laid off in the half-breadth plan, then only half or one side can be represented. The best method, therefore, will be to lay them off in some convenient place on the floor by themselves, whereby both sides may be represented, and there will not be then such confusion in the lines. This, for distinction, may be termed *plan of the transoms*, as *Plate IX. fig. 3*.

The moulding edge of the wing-transom is already described to which the mould is to be made; the filling-transom is next, which lies between the wing and deck; and as it lies horizontally, the description of it will suffice for all the other transoms that come under the deck, which also lie horizontally.

As there is no more trouble in laying-off a transom which is sided straight, and lies level, than there is in laying-off a water-line, strike on each side of the middle line *M*, in the plan of the transoms, *Plate IX. fig. 3*, the half-thickness of the dead-wood or bearding-line, *aa*, taking it from the body-plan, *fig. 2*, (and as low down as the deck-transom the inner post is sided the same); likewise the buttock-lines. Take from the half-breadth plan the square timbers 32, 33, 34, 35, 36, and the proof timbers 1 and 2, and strike them in the plan of the transoms, *fig. 3*, at right angles with the middle line; also strike in the cant of the fashion-pieces *F, M, A*. Then strike a perpendicular line, *P*, in the sheer-plan, *fig. 1*, at the intersection of the upper edge of the wing-transom, at the fore-part of the rabbet; likewise another at right angles with the middle line, at the aft-side of the wing-transom, as *PP*, in the plan of the transoms, *fig. 3*.

Now from the perpendicular *P*, above mentioned, called *perpendicular of the transoms*, take the distance in the sheer-plan, *fig. 1*, to where the upper side of the filling-transom, *F*, intersects the fore-side of the rabbet of the post or bearding-line *B*, and set it off from the same line *PP*, in the plan of the transoms, *fig. 3*, at the middle line, squaring a line across to each bearding-line; which line will be the after-part of the filling-transom at the middle line. Observe where the bearding-line, *C*, of the post, in the sheer-plan, *fig. 1*, comes before the fore-side of the rabbet, to take the aforesaid distance to the bearding-line of the post, as that terminates the after-part of all the transoms; then take the distances in the sheer-plan, *fig. 1*, from the perpendicular line *P*, to where the line representing the upper side of the filling-transom intersects the different buttock-lines 1, 2, 3, 4, and 5, and set them off from the same line *PP*, in the plan of the transoms, *fig. 3*, on their corresponding buttock-lines on each side of the middle line. Then take the distances in the body-plan, *fig. 2*, from the middle line, to where the upper side of the filling-transom, *c*, intersects the square timbers, and set them off on both sides of the middle line on their corresponding timbers, in the plan of the transoms, *fig. 3*; then by pinning a batten through the spots on the buttock-lines and square timbers, to its after-part at the side of the bearding *cc*, the moulding edge or upper side of the filling-transom will be described on one side the middle line; the mould may then be made to that side, and canted over, and the opposite side marked thereby, being sure thus to have both sides alike. This filling-transom

having been laid off horizontally, of course, when moulding the filling-transom, the mould must lie in an horizontal position; but having so little room between the wing and deck-transoms, it becomes necessary to give the filling-transom a round-up between both. Those who would be more correct in laying-off transoms, that have a round upwards, may see the subject farther explained in the following methods.

To lay-off the deck-transom, strike a straight line in the sheer-plan, *fig. 1*, at the under-side of the deck, at the middle line, to take that part of the hang of the deck only, which is terminated between the rabbet of the stern-post and the fashion-piece, as *H*, *fig. 1*. Then take the round of the deck *R*, at every buttock-line, as under the body-plan, *fig. 2*, and set them off below and square to the straight line *H*, in the sheer-plan, *fig. 1*, marking parallel lines thereto, to intersect their corresponding buttock-lines, which gives the moulding edge of the transom. Proceed in the same manner with the lower edge, by striking a line for the lower side of the transom at the middle line parallel to the former; and set the round down, as before, upon any buttock-line.

The upper and lower sides of the deck-transom being obtained on the buttock-lines, in the sheer-plan, *fig. 1*, transfer their heights from the sheer-plan, *fig. 1*, to the body-plan, *fig. 2*, respectively; then by pinning a batten to those heights, the upper and lower sides of the deck-transom, *dd*, may be represented in the body-plan, *fig. 2*.

The lines above mentioned, in the sheer-plan, *fig. 1*, parallel to the sheer of the deck, at the intersection of the buttock-lines and fashion-piece, should be continued aft to the perpendicular *P*; then take the distances from that line, in the direction of the parallel lines, to the buttock-lines and fashion-piece, and set them off square from the said line *PP*, in the plan of the transoms, *fig. 3*, on their corresponding buttock-lines and fashion-piece. Next take the half-breadth from the body-plan, *fig. 2*, at the intersection of the deck, at the side, with the square timbers, and set them off on their corresponding timbers from the middle line, in the plan of the transoms, *fig. 3*; then by pinning a batten to those spots, this forms the moulding edge of the deck-transom *DD*.

The transoms under the deck, all lying horizontally, may be laid off by taking the distances of the buttock-lines and bearding-line from the perpendicular *P*, in the sheer-plan, *fig. 1*, on the upper edge of each transom, and setting them off on their corresponding buttock-lines from the same perpendicular *PP*, in the plan of the transoms, *fig. 3*; and also at the timbers from the middle line in the body-plan, *fig. 2*; and set them off from the middle line on their corresponding timbers in the plan of the transoms, *fig. 3*: a batten pinned to those spots will represent the moulding edges of all the transoms.

To prove the intersection of the transoms with the side of the fashion-piece, which is the end of each transom, as already laid off in the plan of the transoms, *fig. 3*. Thus, where the upper side of the wing-transom in the body-plan, *fig. 2*, intersects the foremost square fashion-piece *S*, level it out to intersect the cant-fashion-piece *c*. Then take the nearest distance from the cant-fashion-piece at that place to the middle line, and set it off from the middle line in the plan of the transoms, *fig. 3*, in the direction of the line of the foremost fashion-piece *F*. In the same manner prove the filling and deck-transoms. Take the distances from the middle cant-fashion-piece to the middle line along the upper side of Nos. 1, 2, and 3 transoms in the body-plan, *fig. 2*, and set them off on the middle cant-fashion-piece *M*, from the middle line in the plan of the transoms, *fig. 3*, as before. Take likewise  
the

the distances from the aftermoft cant-fashion-piece to the middle line for the transoms 4, 5, and 6, and fet them off, as before, on the line for the aftermoft cant-fashion-piece A, in the plan of the transoms, *fig. 3*; to which spots the transoms in *fig. 3*, must agree.

Cut off the ends of the wing, filling, and deck-transoms, at the joint or aft-side of the foremoft fashion-piece F, and transoms Nos. 1, 2, and 3, under the deck at the aft-side of the middle fashion-piece M, and Nos. 4, 5, and 6, at the aft-side of the after-fashion-piece A, as is clearly shewn in the plan of the transoms, *fig. 3*, where the middle fashion-piece is represented as flopt at the under side of the deck-transom, and the after-fashion-piece at the under side of the transom No. 3.

*To make the Moulds and bevel the Transoms.*

The moulds are made of fir battens fayed to the lines already laid off in the plan of the transoms, *fig. 3*, for their aft-sides; and another to their fore-side, at their moulding or breadth at the upper side; which are confined together by battens at each buttock-line, and one at each end to the direction of the fashion-piece, allowing what they are intended to be let into the fashion-pieces; and a broad piece in the middle, to the size of its seating *cc*, with the middle line correctly marked thereon.

The *bevellings* of the transoms are frequently taken from the buttock-lines in the sheer-plan, *fig. 1*, in the following manner. Apply the stock of the bevel E to the upper side of the transoms, in the sheer-plan, *fig. 1*, and the tongue to the buttock-line; but let the tongue be off at the upper and lower sides of the transom, as at the filling-transom in the sheer-plan, *fig. 1*, which gives the exact bevellings of the transoms at their corresponding buttock-lines.

The bevellings for the wing-transom are taken from the margin-line to the under side of the wing-transom, as above. The under side of the wing-transom is transferred from the body-plan, *fig. 2*, to the sheer-plan, *fig. 1*, by the buttock-lines.

The bevellings for the deck-transom may be taken by applying the stock of the bevel parallel to the hang of the deck, at the middle line, and the tongue to each buttock-line; keeping the tongue well at the upper and lower sides of the transom, as before observed, and so must be applied on the transom, by placing the bevel at each corresponding buttock-line, and keeping the stock out of winding with the upper side of the transom at the middle line.

The transoms under the deck may be bevelled by the buttock-lines in the sheer-plan, *fig. 1*, and the bevellings may be taken very exact; but it requires to be very particular in applying the bevel on the transoms; to do which, the stock of the bevel must be kept in the direction of the buttock-lines, at the upper side of the transom, and the tongue teaching to the buttock-line below, which ought to be marked at the lower side of the transom, and not trusting to the bevel's canting promiscuously, for then the bevel may not be exactly square.

When this trouble is taken to bevel the transoms, then they may, when trimmed, be depended upon.

This is a method not to be recommended to those who would be particularly exact, because there can be no more bevellings on the transoms than the number of buttock-lines which intersect the transoms; as for instance, there are only two buttock-lines which cross the lower-transom in *fig. 3*, and one of them is close to the end, which is not sufficient to get the exact form of the lower side of the transom. Therefore, the best way to find the bevellings of those transoms is to lay-off their lower sides, which is very easy to be

effected here, because all the transoms be level. Proceed in the sheer-plan, *fig. 1*, at the under side of the lower transom, to take the distance from the perpendicular of the transom P, to the intersection of each buttock-line, and likewise the bearding-line; and fet them off from the line P P, on their corresponding buttock-lines and bearding-line, in the plan of the transoms, *fig. 3*. Then from the middle line of the body-plan, *fig. 2*, take the distances at the lower side of the said transom to the square timbers, in the same manner as the moulding edges were done, and fet them off on their corresponding timbers, in the plan of the transoms, *fig. 3*, which gives the spots; to which a batten pinned will give the form of the lower edge L L, which is ticked, to distinguish it from the moulding edge. In the same manner may be laid off the lower or bevelling edges of all the transoms.

The distance from the upper or moulding sides of the transoms, to the ticked line for the lower sides, shews how much the transoms are under from a square; only in the distance from the upper to the lower sides of the transoms, in the sheer-plan, *fig. 1*, must be supposed the breadth of the bevelling-board.

By having the lower sides of the transoms laid off, we have an opportunity of taking as many bevellings as may be thought sufficient, without any confinement; therefore, on the lower transom may be placed three bevelling spots, which should be divided equally between the breech and the fashion-piece; then take the nearest distance from the spots on the moulding edge, (which must be first marked on the moulds,) to the ticked line for the lower edge, by sweeping it with a pair of compasses, which shews how much the transom is under from a square at each bevelling spot, as at *a, b, c*, in the plan of the transoms, *fig. 3*, agreeable to the depth of the transom. In the same manner may the bevellings of all the transoms below the deck be taken.

The bevelling for the breech of the transom is taken from the upper side of the transom, and the tongue to the bearding-line in the sheer-plan, *fig. 1*; for the transoms are all supposed to be cut off in the direction of the bearding-line C. The ends of all the transoms, when moulded, are trimmed square from the upper side. But the square, when applied to the end of the wing, filling, and deck-transoms, must be lifted up as much as the transom rounds down, and appears out of winding with a batten in the middle line.

To find the bevelling for the ends of the transoms, when cut off, let the stock of the bevel be placed to the lines of the upper sides of the transoms in the body-plan, *fig. 2*, and the tongue to the cant-fashion-piece, which gives the proper bevelling over the end of the transoms when cut off.

But to find the bevelling for the end of the wing-transom, take the distance square from the middle line to the intersection of the joint, or aft-side of the foremoft fashion-piece, with the end of the wing-transom, in the plan of the transoms, *fig. 3*, and fet it off square from the middle line on the upper side of the transom in the body-plan, *fig. 2*, and level it out till it intersects the cant-fashion-piece. Then apply the stock of the bevel on the line levelled out, and the tongue to the cant-fashion-piece, as at B. This gives the bevelling for the end of the wing-transom, when cut off. But the bevel must be lifted up as much as the wing-transom rounds down at the end, and appears out of winding with a batten kept well with the middle of the wing-transom.

The same must be also done for the bevelling at the end of the filling and deck-transoms.

The points where the transoms under the deck-transom in the body-plan, *fig. 2*, intersect the cant-fashion-pieces, are the proper situations to be crossed on the fashion-piece mould. And

where the lines (before mentioned) levelled out intersect the cant-fashion-piece, is the proper station of the wing, filling, and deck-transoms on the fashion-piece mould for the moulding edge, but not for the direction in which those transoms strike the fashion-piece, because of the round of those transoms; which will be more explained in the following method.

When the lower sides of the transoms are laid off, it is but little trouble to make a slight mould to counter-mould the under sides of all the transoms, by making it only to one arm of the transoms, and then canting it over, to mould the opposite arm. Then, when the breech of the transom is trimmed to the bearding-line, set off the distance from the middle line each way, as far as the bearding-line *cc* is from the middle line in the plan of the transoms, *fig. 3*, to which the transom-mould is made. Then trim the end of the transom square, and set off the bevelling for the end of the transom; then cant the transom over, and applying the mould made for the under side to the breech and bevelling at the end, you have the transom counter-mould, without the assistance of any other bevelling; or they may be set off, to see if they agree with the mould; and if they do, you may be then sure the work is correct.

#### *To Lay-off the Transoms when canted.*

The utility of canting the transoms is, that it greatly assists the conversion of timber, is better for fastening the plank of the bottom, and bolts square to the stern-post. When the transoms have a very great bevelling, it is difficult at the upper edge to get sufficient fastening for the planks, which sufficiently points out the utility of canting them: proceed therefore to the operation, which will require the reader's particular attention; as those minute particulars which cannot so conveniently be displayed on the plate, can only be explained in words.

Dispose of the transoms in the sheer-plan, *fig. 4*; let the wing and filling-transoms be placed level, and the upper side of the deck-transom to the proper hang of the deck; and the other transoms below at the fashion-piece, as much above a level as represented in the sheer-plan, *fig. 4*; so as to make them nearly of an equal opening at the stern-post, and likewise at the fashion-piece. These shew the disposition of the transoms at the middle line.

Now proceed to shew the level view of the moulding edges of all the transoms in the body-plan in the following manner: the wing-transom *a*, and the filling *c*, lying level, they form a segment of a circle in the body-plan, *fig. 5*, to their given round-up. This is the proper curve to which the round-up mould is made for siding these transoms, as before observed. The next is the deck-transom *d*, which being confined to the hang of the deck, and the round of the beam, is the most difficult of any, if executed in a proper manner: it ought to undergo the following operation. The ticked line *H*, in the sheer-plan, *fig. 4*, is the under side of the deck at the middle line, and is intended to be the upper side of the deck-transom at the middle line. Transfer the heights of the ticked line *H*, or upper side of the deck-transom, in the sheer-plan, *fig. 4*, at every square timber, to their corresponding timbers in the body-plan, *fig. 5*; and where the deck at the middle line in the sheer-plan, *fig. 4*, intersects the buttock-lines, transfer them to their corresponding buttock-lines in the body-plan, *fig. 5*: a batten pinned to those spots shews the intersection of the deck at the square timbers, as *H*, in the body-plan, *fig. 5*, supposing the deck had no round-down at the side. Under the line *AA*, for the upper side of the keel, in the body-plan, *fig. 5*, mark the round-up of the gun-deck beam *R*;

and where the ticked line *H* for the deck, at the middle line, in the body-plan, *fig. 5*, intersects the square timbers, square them down to the round of the deck *R*, under the body-plan. The timbers and the buttock-lines are there marked and numbered in the same manner with those from which they were squared down. Take the distance at each place on the round of the deck, under the body-plan, *fig. 5*; square up to the line *AA*, or upper side of the keel (which is the round of the deck at each timber), and set them down below their corresponding timbers, in a perpendicular direction, from the intersection of the deck at the middle line with the square timbers *H*, in the body-plan, *fig. 5*; and from those spots direct them towards the middle line *M*, parallel to the round of the deck under the body-plan, till they intersect the square timbers, which are the proper stations on the square timbers the curve *I* of the deck will make, supposing it to be continued to the outside of the timbers; which is required, in order to find the exact form of the moulding edge of the deck-transom.

Let the buttock-lines in the body-plan, *fig. 5*, be continued down to the round of the deck *R*, under the body-plan; then take the round of the deck at each buttock-line, and set it down below the deck at the middle line *H*, in the sheer-plan, *fig. 4*, on their corresponding buttock-lines, and transfer these spots to the buttock-lines in the body-plan, *fig. 5*; then to those spots on the buttock-lines, and those on the timbers, pin a batten, and it will shew the curve the deck-line at the side will make, if continued to the outside of the timbers, as *I*, in the body-plan, *fig. 5*.

To find the deck at the side in the sheer-plan, *fig. 4*, take the heights at every square timber in the body-plan, *fig. 5*, where they intersect the deck at the side, and transfer them to their corresponding timbers in the sheer-plan, *fig. 4*: by pinning a batten to these spots, with those made before on the buttock-lines, you have the deck at the side, as *I*, in the sheer-plan, *fig. 4*, which is the level view of the moulding edge of the deck-transom.

To find the lower side of the deck-transom in the sheer-plan, *fig. 4*, and likewise in the body-plan, *fig. 5*; this should be done in the same manner as the upper side. If it is intended to be very correct, run the ribband-lines, which will be a proof to the rest of the work, in laying-off the transoms.

To find the level view of the transoms below the deck, in the body-plan, *fig. 5*, observe where the lower and upper sides of the transoms in the sheer-plan, *fig. 4*, intersect the buttock-lines, square timbers, and fashion-pieces; transfer those heights to the body-plan, *fig. 5*, on their corresponding lines, which give the level view of the transoms in the body-plan, *fig. 5*.

To lay-off the cant-transoms, proceed, as before, to make a separate plan, as *fig. 6*. The moulding edges of the wing, filling, and deck-transoms, are laid off so similar to the former, as not to need repeating here. But should the deck-transom have much sheer, and a great round, it would be a further proof of correctness, to take the distance from the perpendicular line *P*, in the sheer-plan, *fig. 4*, to timber 32, in the direction of the sheer of the deck *I*, and set it off square from the line *PP*, in the plan of the transoms, *fig. 6*, which will be further forward than the said timber, as before laid off; then pin a batten to the round of the deck under the body-plan, *fig. 5*, marking the middle line, and the spot that was squared down from the deck at the side, at timber 32, to the round of the deck, and set it off on the new timber 32, in the plan of the transoms, *fig. 6*. This would give the exact spot on timber 32, if the deck was required to hang and round to extremes, in the same manner

as by pinning a batten to the round of the wing and filling-transoms in the body-plan, *fig. 5*, and marking the square timbers, buttock-lines, and square fashion-pieces on the batten; then let the batten lie straight, and it will be the exact half-breadth at every square timber, buttock-line, and fashion-piece, and will give the exact length of the wing-transom.

To lay-off the transoms under the deck, take the distance from the line P, in the sheer-plan, *fig. 4*, to the buttock-lines in the direction of the transoms, and set them off from the line P P, in the plan of the transoms, *fig. 6*, on their corresponding buttock-lines. Take the half-breadths in the body-plan, *fig. 5*, square from the middle line to the intersection of the transoms Nos. 1, 2, 3, 4, 5, and 6, with the square fashion-piece, and set them off square from the middle line in the plan of the transoms, *fig. 6*, to intersect the fashion-piece, marking a line parallel to the middle line, as *a a*, transom No. 6. Then take the distances from the line P, in the sheer-plan, *fig. 4*, in the direction of the transoms, to the fashion-piece, and set them off square from the line P P, in the plan of the transoms, *fig. 6*, on the lines *a, a*, at the intersection of the fashion-piece. Take the half-breadths square from the middle line in the body-plan, *fig. 5*, where the transoms intersect square timber 36, and set them off square from the middle line, in the plan of the transoms, *fig. 6*. Then take the distances from the line P, in the sheer-plan, *fig. 4*, to square timber 36, in the direction of the lines of the transom, and set them off square from the line P P, in the plan of the transoms, *fig. 6*, to intersect their several half-breadths, as at *b, c, d, e*. In the same manner proceed to find all the spots for the square timbers, in order to prove the buttock-lines. This will give the exact form of the moulding edge of all the transoms below the deck, and the station of the fashion-piece on the transom, with the length of the transom at the moulding edge.

To find the direction of the end of the transom, to lie against the side of the fashion-piece, observe in the half-breadth plan where the fashion-pieces intersect the middle line, and square them up to the sheer-plan, as may be seen ticked, and marked K, M, L, calling them the fashion-pieces at the middle line in the sheer-plan, *fig. 4*. Take the distance from the line P, in the sheer-plan, *fig. 4*, to the middle line of the aftermost fashion-piece K, in the direction of the transoms No. 6, and set it off from the line P P, in the plan of the transom, *fig. 6*, on the middle line, and mark the ticked line *g g*, from the spot on the middle line, to the spot on No. 6. transom. This will give the direction to cut off the end of the transom, in order to lie against the side of the fashion-piece.

#### To bevel the Transoms when canted.

Those transoms which are not fixed straight, as the wing, filling, and the deck, are generally bevelled by the buttock-lines, as before observed; but rather than trust to the bevellings only (it being rather difficult to apply them so truly as they should be), lay-off the under sides of all the transoms, and make a slight mould to them. This will correct the bevellings, and make greater dispatch in trimming the transoms. Then there need only (except for proof sake) be taken the bevelling at the bearding-line, and the bevelling at the end; for the mould will give the rest. But observe to be careful in the bevellings at the ends of the transoms; for instance, the ends of the wing and filling-transoms, when they lie level, are to be cut off square; but keep the square as much above the end of the wing and filling-transoms, as they round in their length, and let

the square look out of winding with the middle of the transom. Also the bevel (when applied on the end after it is cut off, in order to bevel the end for counter-moulding) must be kept as much above the end of the transom, and look out of winding with the middle of the transom.

As the bevelling for the end of the deck-transom is taken against the cant-fashion-piece by a level line in the body-plan, *fig. 5*, it must be observed how much the transom at the middle line in the sheer-plan, *fig. 4*, is below a level (suppose one foot). Then place a batten at the middle line on the transom, and lift the foremost end of the batten up till it becomes level, as supposing the transom to be in its place: then proceed with the square and the bevel for the end of the transom, in the same manner as for the wing and filling, looking out of winding with the batten at the middle line.

To bevel the transoms, which are canted in the sheer-plan, *fig. 4*, proceed in the same manner as in bevelling the cant-timbers, by making a parallel line to the moulding edge. Therefore lay-off the bevellings of the transoms, by squaring a line from the upper side, where it intersects the line P, in the sheer-plan, *fig. 4*, to the under side, as the ticked line *a* at the lower transom. Take the distances from where the squared line, *a*, crosses the lower edge in its cant direction, to the bearding-line *c*, and to all the buttock-lines, and set them off square from the line P P, on their corresponding lines, in the plan of the transoms, *fig. 6*. Where the bearding-line *c*, in the sheer-plan, *fig. 4*, proves to be square from the direction of the transom, as it is, or very nearly so, at the lower transom, then the bearding for the moulding edge, and likewise for the bevellings, will come as near together in the plan of the transoms, *fig. 6*. This may sufficiently prove that the method of bevelling is correct.

Where the under side of the lower transom intersects the square timbers and square fashion-piece in the body-plan, *fig. 5*, take the nearest distances from thence to the middle line, and set them off square from the middle line, in the plan of the transoms, *fig. 6*, striking lines parallel to the middle line, as at *i i*. Then take the distances from the squared line *a*, in the sheer-plan, *fig. 4*, in the direction of the under side of the lower transom, to the square timbers and fashion-piece T, and set them off square from the line P P, on their corresponding lines last struck, in the plan of the transoms, *fig. 6*. To these spots, and those on the buttock-lines, pin a batten, and it will represent the ticked line, *b b*, within the lower transom, which will shew how much the lower transom is under from a square, agreeable to the depth of the transom. Take the distance from the squared line *a*, in the sheer-plan, *fig. 4*, to the ticked perpendicular K, which is the after-fashion-piece at the middle line; and set it off from the line P P, on the middle line, in the plan of the transoms, *fig. 6*, and mark the ticked line, *m*, from thence to the spot on the fashion-piece, which will be a line parallel to the ticked line *g*, before marked to cut off the end of the transom; and the distance between the two ticked lines shews how much the end of the transom is under from a square, agreeable to the depth of the transom.

The ticked line *b b*, in the plan of the transoms, *fig. 6*, which is for the bevellings, is the line to make the temporary mould to, in order to counter-mould the transom; and by cutting off one end of the mould to the thwartship-line for the breach of the transom, and cutting off the others to the ticked line *m* for the end of the transom, when the mould is applied to the under side of the transom, it will be easily perceived if the work be true.

To find the exact bevelling to be applied over the end

of the tranfom, after the end is cut off, in order to counter-mould the tranfom, proceed in the following manner. Where the upper and lower fides of the lower tranfom interfect the after-cant-fashion-piece P, in the body-plan, *fig. 5*, level them out to interfect the after-cant-fashion-piece O. Where the upper fide of the lower tranfom interfects the perpendicular ticked line K (which is the after-fashion-piece in the sheer-plan, *fig. 4*), transfer that height to the middle line, in the body-plan, *fig. 5*; and from thence draw a ftraight line to the upper fide of the lower tranfom, on the cant-fashion-piece, as the ticked line *e*; to which line fix the flock of a bevel, as at B, and the tongue to the cant-fashion-piece O, as low down as the fpot for the lower fide of the tranfom. This is the proper bevelling to be applied on the end of the tranfom, after the end is cut off, in order to counter-mould the tranfom. The ticked line *e*, to which the flock of the bevel is placed, is the direction of the tranfom to be croffed on the fashion-piece mould. The bevel B, which is represented in the body-plan, *fig. 5*, fhewing the bevelling of the end of the lower tranfom, fufficiently proves the utility of canting the tranfoms; for, by having fo little bevelling, it greatly affifts the conversion of timber, as well as that it muft certainly be better for the fecurity of the plank of the buttock.

*To Lay-off a Square-Tuck, Plate IX. Laying-off C.*

We have already explained the utility of the tranfoms in compofing the itern-frame, by which method moft fhips are inclofed abaft. But yachts and cutter-built veffels are, owing to their clearnefs of run abaft, inclofed by a fquare tuck, by which room is gained; and, when properly put together, this mode of conftruction is, perhaps, ftronger than tranfoms would be in veffels of this defcription.

The tuck propofed to be laid off is that of the royal yacht, *Plate XIII*. But that the reader may be led progressively on from the eafieft to the moft difficult part of the operation, we fhall firft propofe a fquare tuck, the fides of which are to be out of winding, or in the fame direction as the rabbet of the poft, in confequence of which the wing-tranfom muft be ftraight athwartfhips, and the whole will be one flat furface (fimilar to the tranfoms of boats), or a fection of the vefel cut athwartfhips, but not in a perpendicular direktion, which is the only difference between it and the fquare timbers; and as the fection is agreeable to the rake of the itern-poft, it confequently follows, that the laying it off muft differ from the fquare timbers in the operation.

The horizontal view of the tuck muft firft be represented in the body-plan, *fig. 8*, which is done in the following manner: ftrike a horizontal line in the sheer-plan, *fig. 7*, at the height of the wing-tranfom at the fide, as at 5; and likewise as many horizontal lines below that as may be thought fufficient; and where they interfect the aft-part of the rabbet of the poft *a*, fquare them down to the half-breadth plan, *fig. 9*; then transfer their heights to the body-plan, *fig. 8*; and where they interfect the fquare timbers 21, 22, 23, 24, 25, and P 1, in a horizontal direktion, take thofe diftances from the middle line, and fet them off upon their correffponding timbers from the middle line, in the half-breadth plan, *fig. 9*; then by pinning a batten to thofe fspots, the horizontal lines 1, 2, 3, 4, 5, and 6, will be represented; then take their diftances from the middle line, in the half-breadth plan, *fig. 9*, where they interfect the lines fquared down from the sheer-plan, and fet them off from the middle line on their correffponding horizontal lines, in the body-plan, *fig. 8*; then by pinning a

batten to thofe fspots, the horizontal view of the tuck, *a*, will be represented in the body-plan, *fig. 8*, as high as the wing-tranfom at the fide. But was the head of the fashion-piece required to run up, to take a bolt or two through the heel of the fide counter-timber, proceed in the fame manner to run a horizontal line or two above that at the fide of the wing-tranfom; fay, one at the upper fide of the wing-tranfom at the middle line; then run the main half-breadth line in the half-breadth plan, *fig. 9*; then, where the laft horizontal line and main height of breadth line interfect the aft-fide of the rabbet *a*, in the sheer-plan, *fig. 7*, fquare them down to the half-breadth plan, *fig. 9*, and take their diftances from the middle line in the half-breadth plan, *fig. 9*, to where they interfect the horizontal line 6, and the main half-breadth line, and fet them off from the middle line on their correffponding horizontal lines, in the body-plan, *fig. 8*; then by continuing the curve, *a*, upwards through thefe fspots, the horizontal view of the tuck will be continued up to the height of breadth.

Now, where the horizontal view of the tuck in the body-plan *a*, *fig. 8*, interfects the bearding-line *b*, take that height, and transfer it to the sheer-plan, *fig. 7*, ftriking there the horizontal line S, which represents the feating of the tuck; then take the diftance from the feating of the tuck, in the sheer-plan, *fig. 7*, on the rake, (in the direktion of the rabbet of the poft *a*) to the refpective horizontal lines and height of breadth, and fet them up the middle line, from the horizontal line S, at the feating of the tuck, in the body-plan, *fig. 8*; ftriking a horizontal line to the rake, at every height, as fhewn by the fine-ticked lines; then, where the horizontal view of the tuck, *a*, interfects the horizontal lines firft ftruck, carry it up parallel to the middle line, to their correffponding horizontal lines on the rake; which will give the fspots through which the fine-ticked curve is to pafs, that will represent the proper fhape of the tuck, agreeably to the rake, as *c*; and the line to which the fashion-piece mould muft be made.

The bevellings for the fashion-piece may next be taken, by proceeding as follows. The aft-fide of the rabbet of the poft *a*, in the sheer-plan, *fig. 7*, represents the aft-fide of the fashion-piece of the tuck; therefore, take the fiding of the fashion-piece, and fet it off afore the rabbet, and fquare thereto; then, by ftriking a parallel line to the aft-fide *a*, the fore-fide of the tuck *b* will alfo be represented; next, from the feating of the tuck S, on the aft-fide, fquare the line C from the rabbet to the fore-fide; and from its interfection at *c*, take the heights of the horizontal lines up the fore-fide, and fet them up on the middle line from the horizontal line S, at the feating of the tuck, in the body-plan, *fig. 8*; ftrike horizontal lines for the fore-fide of the fashion-piece, as diftinguifhed by the long-ticked lines; then, where the fore-fide of the fashion-piece *b*, in the sheer-plan, *fig. 7*, interfects the horizontal lines and height of breadth, fquare it down to their correffponding horizontal line and main half-breadth, in the half-breadth plan, *fig. 9*; at which interfections take the diftances fquare to the middle line, and fet them off from the middle line on their correffponding horizontal lines, for the fore-fide of the fashion-piece, in the body-plan, *fig. 9*. Continue the fore-fide of the fashion-piece down to the bearding-line *d*, as you fee ticked in the sheer-plan, *fig. 7*; then take the diftance from the interfections of the fquared line at the feating *c*, down the fore-fide of the fashion-piece to the horizontal line 1, and where it interfects the bearding-line *d*, and fet it off in the body-plan, *fig. 8*. Below the horizontal line S, at the feating of the tuck down the bearding-line, ftrike a horizontal line for No. 1, and proceed as before directed to obtain the half-breadth

## SHIP-BUILDING.

breadth spot on the half-breadth and body-plans, *figs.* 9 and 8; then to all those spots pin a batten, and mark the curve which shall intersect the bearding-line, and the fore-side or bevelling-edge, *d.* of the fashion-piece will be represented in the body-plan, *fig.* 8.

The aft-side and fore-side appear now in their proper shape, in the body-plan, *fig.* 8, and of the same form as the fashion-piece, when trimmed and laid flat with the aft-side upwards, as then both edges will be seen, in consequence of its being a standing bevelling; therefore, the distance from the line represents the aft-side to the line of the fore-side, taking the nearest distance, as at *e*, which will shew how much the bevellings are standing, or without a square, in the breadth of the bevelling-board, which should be equal to the siding of the fashion-piece.

When the mould is made to the ticked line, *c*, of the aft-side, the heel of it must be cut off well with the line for the seating of the tuck, and likewise well with the middle line, in order that it may dovetail and bolt into the stern-post. Mark also on the mould the bearding-line, or side of the inner post. The different firmarks for the ribbands must be marked on the moulds; but, in order that the stations of the ribbands may be correctly marked, observe where the diagonal lines intersect the horizontal view of the tuck *a*, in the body-plan, *fig.* 8, and carry them up parallel to the middle line, to the line for the aft-side of the fashion-piece *c*, to which the mould is made. This will be their proper stations or upper sides, and may thence be marked on the mould.

The bevellings may be taken at the different firmarks or ribbands, and set off where taken, as the bevel at the seventh ribband, which will shew it more clearly. The ticked line *g*, drawn parallel to the flock of the bevel, is the same distance from the outside of the bevel, as the fashion-piece is sided. Then draw a line square from the flock of the bevel to the ticked line *g*; and where it intersects the ticked line *g*, as at *b*, set off from *b* to *i* the same distance as the fore-side is from the aft-side at that place, as before directed, and open the tongue of the bevel to *i*. This will shew the bevelling of the fashion-piece at that place. The bevel is to be applied square from the moulding edge.

Run in the half-breadth plan, *fig.* 9, the diagonal 7, although the ending of it only differs from those explained before, and need only be described. Transfer the height from the body-plan, *fig.* 8, where the diagonal 7 intersects the horizontal view of the fashion-piece *a*, and set it up in the sheer-plan, *fig.* 7, at the aft-side of the fashion-piece; and from its intersection there, square it down to the half-breadth plan, *fig.* 9; then take its distance in the body-plan, *fig.* 8, from the middle line to the horizontal view of the fashion-piece *a*, in its diagonal direction, and set it off from the middle line, in the half-breadth plan, on the line squared down, which gives its ending at the fashion-piece. In the same manner transfer its height where it intersects the upper side of the wing-transom, in the body-plan, *fig.* 8, and set it up in the sheer-plan, *fig.* 7; and where it intersects the aft-side of the fashion-piece, square it down to the half-breadth plan, *fig.* 9; then take the distance from the middle line, in the body-plan, *fig.* 8, as before, to the upper side of the wing-transom, and set it off from the middle line, in the half-breadth plan, *fig.* 9, on the line last squared down; then mark a line through those spots, as the long-ticked line *a*, in the half-breadth plan, *fig.* 9, which will be the true ending of the diagonal 7, or any diagonal crossing the wing-transom and fashion-piece.

Square tucks of lighters are like those above described.

and the transoms of boats are laid off in a similar manner, but composed of only one piece athwartships, and their upper side is bounded by the upper side of the sheer. But the tucks of yachts (or frigates, if built of fir) partake of the round-forward of the wing-transom, which causes the fashion-pieces to take a part of it also the whole of their length, which makes them rather more difficult to be laid off. But, supposing the former to be clearly understood, we shall give a description of a tuck, the outside of which is to round-forward, in its finished state.

Suppose a flat surface, of thin deal (in length from the head of the fashion-piece or height of breadth to the seating of the tuck, and in breadth to the outside of the transom) was placed with one edge to the rabbet of the post, and the other edge bent round to a curve, as much as the outside of the tuck is intended to round-forward, in which position suppose it to be confined; then draw the shape of the outside of the tuck or fashion-piece down to the post, and cut it out. The true shape of the tuck or fashion-piece is now shewn as it is to be trimmed, and as it will appear in its finished state. Then take it from its position, and lay it flat, letting the round be unconfined; and it will then appear as it is required to be laid off in the body-plan, in order to make the mould therefrom.

The fashion-pieces for the square tuck being already laid off, the same horizontal lines, &c. may be transferred to the sheer and body-plans, *figs.* 10 and 11; then proceed to lay it off upon the flat, agreeable to the rake of the rabbet of the stern-post, as before directed, with this difference, having no round-aft made, but one straight line in the thwartship view, in the sheer-plan, *fig.* 7, which was the aft-part of the rabbet of the stern-post; but, in the present square tuck, where the head of the fashion-piece is carried forward, to connect with the end of the wing-transom, the moulding edge of the fashion-piece forms a serpentine line.

Therefore, where each horizontal line intersects the aft-part of the rabbet of the post *a*, in the sheer-plan, *fig.* 10, square down the distances to the middle line of the half-breadth plan, *fig.* 12, making of spots; then upon the horizontal line, No. 5, at the height of the wing-transom, at the side, set off from the aft-side of the rabbet of the post *a*, the round-forward of the wing-transom, in the sheer-plan, *fig.* 10, and square it thence down to the half-breadth plan, *fig.* 12; upon which set off the half-breadth of the wing-transom, and thence sweep a curve, the centre of whose radius being in the middle line, shall cut the spot for the said horizontal line, in the middle line of the half-breadth plan, *fig.* 12, which will represent the aft-side of the wing-transom *a*, at the height of the horizontal line at the side. Now, from the other spots squared down on the middle line of the half-breadth plan, sweep curves with the same radius, and they will be parallel to the curve of the wing-transom *a*. The horizontal lines being transferred from the half-breadth plan, *fig.* 9, to *fig.* 12, take the distances square from the middle line in the half-breadth plan, *fig.* 12, to where the horizontal lines intersect their respective curves for the aft-side of the tuck, and set them off from the middle line on their corresponding horizontal lines, in the body-plan, *fig.* 11; a batten pinned to those spots will shew the horizontal view of the tuck *a*, in the body-plan, *fig.* 11. Also, where the horizontal lines in the half-breadth plan, *fig.* 12, intersect their respective curves, square the distances up to their corresponding horizontal lines in the sheer-plan, *fig.* 10; and by drawing a curve to pass through those spots, the thwartship view of the aft-side of the fashion-piece, *b*, will be represented in the sheer-plan, *fig.* 10; and what the thwart-

thwartship view of the aft-side of the fashion-piece leaves the rabbet of the stern-post, in order to be conformable to the wing-transom at the side, is easily perceived by the shaded lines.

Till this thwartship view of the aft-side of the fashion-piece, *b*, be shewn in the sheer-plan, *fig. 10*, the ribband-lines cannot be truly ended, although the operation is the same as before described.

Though the aft-side of the fashion-piece *b*, in the sheer-plan, *fig. 10*, leaves the rabbet of the stern-post at the head conformable to the end of the wing-transom, yet a square line at the seating must be drawn as before, to lay-off the tuck on the flat; therefore, take the nearest distances from the square line *a*, in the sheer-plan, *fig. 10*, to where each horizontal line crosses the aft-side of the fashion-piece *b*, and set them up from the horizontal line *S*, in the body-plan, *fig. 11*, striking horizontal lines, as distinguished by a fine tick.

Then take the half-breadth of the wing-transom, in the body-plan, *fig. 11*, square from the middle line, and set it off from the middle line, on the line *AA*. Next, fix one leg of the compasses at the end of the wing-transom, in the sheer-plan, *fig. 10*, and take the nearest distance to the aft-part of the rabbet of the stern-post *a*, which is square from the rabbet, as the line *e*; and set it off square from the line *AA*, at each end of the transom *bb*; and sweep the arc *cc*, which gives the round-aft of the tuck at any height, square from the rabbet of the stern-post. Square down the fine-ticked lines, or horizontal lines, 2, 3, 4, 5, 6, and 7, on the rake where they intersect the horizontal view, *a*, of the fashion-piece in the body-plan, *fig. 11*, to the round-aft line, on a square under the body-plan. Then take their distances from the middle line, on the curve *cc*, or round-aft, on a square, and set them off from the middle line of the body-plan, *fig. 11*, on their corresponding horizontal lines; then pin a batten to these spots, and to where the seating intersects the post, and it will give the form of the aft-side of the fashion-piece *d*, to which the mould is to be made, that will agree with the other timbers, when in their places.

To be correct with the length of the wing-transom on the flat, take the half-breadth from the body-plan, *fig. 11*, on the round for the upper side of the transom; then continue the end of the transom in the half-breadth plan, *fig. 12*, square out from the middle line, as at *c*; on which (square from the middle line) set off the half-breadth taken on the round from the body-plan, *fig. 11*, and from that spot sweep an arc to break into the middle of the transom, at the middle line, as represented by the dotted line *a*; then from the before mentioned spot, or end of the wing-transom at *b*, take the half-breadth round the dotted curve to the middle line, and set it off from the middle line in the body-plan, *fig. 11*, round the curve, for the upper side of the transom. This will give the exact length of the transom on the round-aft of the tuck.

Previous to the laying-off of the fore-side of the fashion-piece, it will be proper to understand in what manner the fashion-piece is to be moulded and trimmed, particularly on the fore and after-sides.

Make a mould to the moulding, or outer edge of the fashion-piece laid off on the flat, as the fine ticked line *d* in the body-plan, *fig. 11*. The upper end may be made as high as the height of breadth, or horizontal line 7, and the lower end may reach to the seating on the post. Let the upper end of the mould be cut off well with the direction of the horizontal line 7, and let the heel be exactly perpen-

dicular at the side of the inner post. Make another mould to the round-aft, on a square *cc*, as shewn under the body-plan, *fig. 11*, and of a parallel breadth, like part of a beam-mould. Make it as broad as the fashion-pieces are intended to be sided, and let the midship-end be well with the side of the inner post, and cut off parallel to the middle line. Let the side-end correspond well with the moulding edge of the fashion-piece, and cut off agreeable to the round of the side when the mould lies in its proper place, underneath the body-plan, *fig. 11*. Let the fashion-piece be sided sufficiently for the wing-transom to dovetail into the aft-side of it, and let the fore-side of the fashion-piece, that runs above the wing-transom, be of sufficient length to receive the bolts of the side stern-timber, and long enough at the heel to meet at the middle line.

When the fashion-piece is roughly sided on the aft-side, so as to lay the mould on the aft-side, to mark the upper and lower end nearly, then cut off the head by the mould for the thwartship-way, and the fore and aft-way, square. Then fasten the round-aft mould, that is made to the siding, on the head of the fashion-piece, by which may be trimmed the fore and after-sides of the fashion-piece out of winding, by lines parallel to the middle line. Thus will you have the best opportunity of seeing how to convert the piece, by seeing both sides at once. Then will the fashion-piece be of a parallel thickness from one end to the other, by all lines that are parallel, whether perpendicular or horizontal.

#### *To Lay-off the Fore-side of the Fashion-Piece.*

Having the siding of the fashion-piece on a square, set it off in the sheer-plan, *fig. 10*, square from the rabbet of the stern-post *a*; then with compasses take the siding of the fashion-piece in the direction of the horizontal lines, and set it off square from all the aft-sides of the horizontal lines, prolonged in the half-breadth plan, *fig. 12*, on each horizontal line, and square them up on their corresponding lines in the sheer-plan, *fig. 10*. Then pin a batten to those spots, and the fore-side of the fashion-piece *e* will be represented. Take the heights above and below the squared line *d*, in the sheer-plan, *fig. 10*, to the intersection of each horizontal line with the fore-side of the fashion-piece *e*, in the same manner as the aft-side was done; and set off above and below the ticked line *S*, in the body-plan, *fig. 11*, and strike horizontal lines, as there distinguished by long-tick. Then take the half-breadths in the half-breadth plan, *fig. 12*, to the fore-side of the fashion-piece on the horizontal lines, square from the middle line; and set them off square from the middle line on to the line for the round-aft, on a square *cc*, under the body-plan, *fig. 11*. Then take them off again on the round-aft line, and set them off from the middle line, on their corresponding horizontal lines in the body-plan, *fig. 11*. Then pin a batten to those spots, and the form of the fore-side of the fashion-piece *e* will be agreeable to the siding proposed.

The aft-side of the fashion-piece not being straight, will render it more troublesome than useful, to run lines in order to trim the outside of the fashion-piece by bevellings; therefore it would be better to make a mould to the fore-side *e*, and trim a spot to lay to the side of the inner post or dead-wood; and set off a bevelling for the outside at the main-breadth, as at *B*, *fig. 12*.

Mark the line at the seating *S*, in the body-plan, *fig. 11*, on the mould for the aft-side, and on the mould for the fore-side; and when the aft-side is moulded, and the side trimmed to lay to the inner post, mark the spot *b* square from the aft-side

## SHIP-BUILDING.

aft-side to the fore-side, to which place the spot *b*, on the mould for the fore-side, must properly correspond; and the head of the mould must be kept well with the spot to the bevelling at the main-breadth. The mould lies then in its proper place to mould the fore-side of the fashion-piece.

It is customary, in boats, for the planks of the bottom to run through to the aft-side of the transom, and sometimes to the aft-side of the fashion-piece of lighters; but in larger vessels it is better to rabbet the fashion-piece; for when the planks of the bottom are rabbetted into the fashion-piece, and the inside of the butts left longer than the outside, the planks are apt to be pressed to the timbers on caulking their ends; while, on the contrary, when the planks run through the fashion-piece, they are not able to bear the force that is required to be made by caulking their ends sufficiently. In vessels of this class, likewise, the ends of the planks would be liable to be started off by accident.

The fashion-piece, as it is laid off, both fore and aft-sides, is conformable to the timbers of the body, being for that reason easier understood; but when the fashion-piece is moulding, be careful to leave enough without the lines for the thickness of the plank; which may be found exactly by holding a batten at the outside of the fashion-piece, at several places, parallel to the lines for the fore and aft-sides of the fashion-piece, and square from the lines.

Then extend the compasses to the thickness of the bottom plank, or otherwise run as many fictitious diagonal lines as shall be necessary, and square from the moulding edge of the fashion-piece. Then set off the thickness of the plank of the bottom, and lay off the extreme outside of the fashion-piece, likewise the aft-side, observing the round in the direction of the diagonal line, whereby a mould may be made to the aft-side, at the extreme breadth; and the outside may be trimmed by bevellings from the diagonal lines. But great care must be taken to place each diagonal line square from the moulding edge of the fashion-piece; and then, as the fashion-piece at the aft-side will wind or twist in the direction of the diagonal lines, the tongue of the bevel must not cant at all the bevelling spots, exactly in the direction wherein the diagonal lines were laid off; for the diagonal lines at the middle line (suppose in the sheer-plan) are parallel to the upper side of the keel; and are canted down similar to the flap of a table, as before observed; in which direction the tongue of the bevel ought to cant, when the bevellings are taken from the diagonal lines.

The fashion-pieces are rabbetted on their aft-sides, to receive the planks of the tuck; but do not take the rabbet to low down as where it intersects the post, but leave it square some inches above it, that the midship piece may be gotten in its length as it rabbets into the post, and it will also leave a better butt for caulking, as shewn in the body-plan, *fig. 11*.

The wing-transom mould must be made to the fine ticked curve *d*, in the half-breadth plan, *fig. 12*. The bevelling of the wing-transom will be the same athwartship on the aft-side, which bevelling is the rake of the rabbet of the post *a*; and the wing-transom is rabbetted at the aft-side at the lower edge for the planks of the tuck, and at the upper edge for the planks of the lower counter, (if thought proper,) therefore the heels of the stern-timbers should be placed as much before the aft-part of the wing-transom as the thickness of the planks of the lower counter.

To prevent any error in the true height of the fashion-pieces, let the firmark *e*, in the body-plan, *fig. 11*, be correctly marked on the mould and side of the stern-post, so

that when the heels of the fashion-pieces are letting-on the post, those firmarks must exactly agree.

*To Lay-off the several Parts of the Head, Plate X. Laying-off D.*

The knee, cheeks, rails of the head, and block for the figure, must be laid off to their full size on the floor from *Plate I.*, which is the horizontal and thwartship view, when the cheeks, rails, &c. are fixed in their places.

*To make the Mould to the Knee of the Head.*—The lower part of the knee at the fearl, as at *X*, *Plate X. fig. 1*, *Laying-off D*, may be made of fir-board about an inch thick, and up the fore-part of the knee and stem, as high as the cutting-down and feating of the figure; but these need be no broader than about five inches for lightness, as at *39, 39, fig. 1*. Then across the mould are fastened battens, which not only keep the mould together, but the manner of siding the knee is expressed thereby. Thus, take any perpendicular, as at *24, fig. 1*, and level out the several heights *13, 14, 15, 16, and 17*; and at *13* and *17* set off the half-siding of the stem, striking a line thereto. Then let fall a perpendicular from the fore-side of the knee at the upper part, as at *25, fig. 1*, and set off the half-siding of the knee at *4*, and at *12*, and strike a line. Strike the lines across the knee of the head, where it is intended to have the upper side of the battens, as at *1, 2, 3, &c. to 12*. Then, to determine on the siding of the knee at the fore part, pin a batten from the upper part of the knee round the fore-side, marking thereon the lines *1, 2, 3, &c.* Then apply the batten to the perpendicular *25, fig. 1*, keeping it fast at the upper end, and mark on the perpendicular the spots *1, 2, 3, &c.* Then from the perpendicular *25, fig. 1*, take the half-siding at each spot, and set them off on their corresponding lines at the fore-side of the knee: proceed in the same manner for the half-siding of the stem at *24, fig. 1*, and strike in the lines as ticked across the knee. Then battens being made to those lines, and nailed across the mould, the half-siding of the knee may be readily set off at the upper side of each batten, and the knee, when put together, may be trimmed straight from the fore-side to the stem or aft-side of the knee: the cutting-down, as at *1, 2, 3, and 4, fig. 1*, is sided in the same manner.

*To make the Mould to the Gripe, G, fig. 1.*—The gripe is only the completion of the knee to the keel, and the mould is made so similar to the knee above as to need no further description.

*To make the Moulds to the Cheeks.*—The cheeks must be laid off to their moulded size on the half-breadth plan, *fig. 2*, as at *C, C*, to the main half-breadth line, allowing the thickness of the plank, as at *R*, and against the side of the knee. Another mould must be made to the slight of each cheek, in the sheer-plan, *fig. 1*, at *C*, or upper cheek; and *L, C*, the lower cheek, from the heel of the figure *Z*, to reach as far aft as the cheeks are there shewn, marking a firmark at the fore-side of the stem. Then, to mould the cheeks to their proper slight, draw off the knee-arm to the mould made in the half-breadth plan, marking on the piece the fore-side of the stem from that mould: then fastening the slight-mould to the knee-arm of the cheek, observing to keep the firmark well at the fore-side of the stem, and keeping the mould parallel to the middle line, let the cheek be trimmed out of winding by the thwartship lines, or lines which are square from the mould. Then there is a certainty, when the cheek is throated, no angle will appear in the throat, as there will be sometimes by the usual method, particularly in full-bowed ships, where the sheer springs more than the slight of the cheeks. When the side-arm of the cheek is trimmed

trimmed by a mould made to the sheer of the ship, and the fore and aft-arms by the flight of the cheeks laid off on the floor, there will sometimes be a very disagreeable throat, which cannot happen when trimmed by the above method. Although the side-arm may not hang so much as the sheer of the ship, yet it will not look disagreeable, because the throat of the cheek is the only part that takes the flight.

*To lay-off the Head-Rails.*—Strike in the perpendiculars Z and Y from the fore-side of the figure, and foremost end of the upper rail in the sheer-plan, *fig. 1*, down to the half-breadth-plan, *fig. 2*. Determine on the half-breadth of the lacing, as at 1, 2, *fig. 2*, as the foremost end of the upper rail comes against it. The after end lays against the plank at the beak-head timber, from whence strike a straight line to the lacing at its fore end. Then set off the siding of the rail, allowing the thickness of the lining, and strike the line P, or outside; which being the fight-side of the rail when in its place, is the properest to be laid off.

Strike the horizontal line 32 at the upper part of the foremost end of the upper rail, in the sheer-plan, *fig. 1*. Then square up to the line 32 the aft-side of the stem-timber 20, and as many lines at equal distances as may be needful, and number them 1, 2, 3, &c. above the line 32, as shewn in *fig. 1*. Set off the same stations from perpendicular Y, on the middle line in the half-breadth plan, *fig. 2*, and square them out to the line P, or outside of the main-rail, numbering them, as before, at the middle line; then square them out from the line P. Take the distances from the line 32 in the sheer-plan, *fig. 1*, to the upper and lower parts of the main-rail at each perpendicular line, and set them off on their corresponding numbers in the half-breadth plan, *fig. 2*, which was squared out from the line P; and then, by pinning a batten to these spots, it will give the form of the main-rail, and it will shew the same form, when in its place, as that in the sheer-plan, *fig. 1*. Where the lines squared out from the middle line in the half-breadth plan intersect the inside of the main-rail, strike them from thence square from the line P to the rail already laid off, and take the distances on these lines from the line P to the upper part of the rail, and set them down from the line 32 in the sheer-plan, *fig. 1*, on their corresponding perpendiculars; which will give the inside of the main-rail in the sheer-plan, *fig. 1*; as the ticked line, which rises above the middle of the rail forward, being the upper line, and below towards the after end as the after part, falls below the outside. The inside of the rail at the lower edge must be set off in the same manner in the sheer-plan, in order to lay off the timbers exactly.

Strike the ticked line in the plan of the rails in the half-breadth plan, *fig. 2*, which is the line to which the chamfer at the under side of the rail the mouldings are intended to be wrought to. This must likewise be laid off in the sheer-plan, because in a thwartship view this is the proper sight of the lower edge of the rail: for the lower part of the rail in the sheer-plan (which was first laid off in order to lay off the rail to its proper cant in the half-breadth plan) may now be rubbed out, when the rail is supposed to be chamfered or wrought.

In the half-breadth plan, *fig. 2*, where the lines squared out from the middle line intersect the ticked line before-mentioned, strike them from thence square from the line P to the lower part of the rail laid off; then take the distances on those lines from the line P to the lower part of the rail, and set them off from the line 32 in the sheer-plan, *fig. 1*, on their corresponding perpendiculars. This gives the lower part of the rail in the sheer-plan, at the chamfer, being the fight part of the rail when trimmed and in its place.

Before the main-rail is canted, as in the half-breadth plan, *fig. 2*, the proper form of it cannot be ascertained in the sheer-plan, *fig. 1*; for the rail, when canted in order to make the mould, must be gradually diminished from one end to the other, and from thence transferred to the sheer-plan; for instance, the middle line at the after-part of the rail in the sheer-plan, is the aft-part of the rail at the outside; so that from thence to the fore-side of the rail shews less than the rail in the middle; also, at the foremost end the rail will not shew so much as it does in the half-breadth plan; whereas in the middle it shews the same.

Before the middle rails can be canted in the half-breadth plan, *fig. 2*, to their proper spread, proceed in the following manner; strike a horizontal line from where the aft-side of the stem-timber 20, in the sheer-plan, *fig. 1*, intersects the upper side of the upper cheek, as the line 27, in *fig. 3*. Take the heights from the upper side of the upper cheek, at the perpendicular line 7, in the sheer-plan, *fig. 1*, to the upper and lower parts of the three rails L, M, and N, and set them up from the horizontal line before-mentioned in *fig. 3*, as you see ticked at L, M, and N. Then take the distances from the middle line in the half-breadth plan, *fig. 2*, at the line 7, to the outside of the main-rail; likewise to the inside, and the ticked line for the chamfer of the rail at the under side; and set them off on their corresponding lines in *fig. 3*, and draw the thwartship section of the main-rail. Set off in the half-breadth plan the half-thickness of the knee S Y of the head, and the moulding of the upper cheek C C; then take the half-thickness of the knee at 7, or aft-side of the stem-timber in the half-breadth plan, *fig. 2*, and set it off from the middle line *u* in the plan of the timber, *fig. 3*, on the line 27. Then determine the breadth of the timber at the upper side of the cheek, and pin a batten to the curve for the outside of the timber. Then in the plan of the timber, *fig. 3*, determine on the half-breadths of the middle rails L and M; and transfer them from thence to the half-breadth plan, *fig. 2*, at the aft-side of the stem-timber. Then set off the distance of the foremost end of the rails from the middle line, and strike in the two lower or middle rails N, O, in the half-breadth plan, *fig. 2*.

The middle and lower rails being determined in the half-breadth plan, *fig. 2*, the outsides of them, being the fight-sides, are the properest to be laid off. The outside of the middle rail is marked O, and the outside of the lower rail N. Where the upper sides of the middle rail M, and lower rail L, in the sheer-plan, *fig. 1*, intersect the aft-side of the hair-bracket H, strike the horizontal lines 33 and 34, answerable to those in the half-breadth plan, *fig. 2*.

Where the lines 1, 2, 3, &c. which are square from the middle line in the half-breadth plan, *fig. 2*, intersect the lines O and N, let them be squared out from the lines O and N, in the same manner as was performed for P. Then take the distances from the lines 33 and 34, in the sheer-plan, *fig. 1*, (at the same perpendiculars as before,) to the upper side of the middle and lower rails, and set them off in the half-breadth plan, *fig. 2*, from their corresponding lines O and N, on the lines squared out. This gives the form of the upper sides of the middle and lower rails, which is sufficient to shew the method of laying off each rail, agreeable to their different cant or spread. The lower side of the rails is formed by a diminishing line to the moulding or depth of the rail at each end.

It is very seldom that the middle and lower rails are laid off on the floor only; the main or upper rail, when trimmed, is gotten up into its place, and moulds are there made to the head-timbers, and then the middle and lower rails are spread and equally divided thereon between the upper rail

## SHIP-BUILDING.

rail and upper cheek, and the moulds made to them when their situation is determined on.

But in order to shew what may be performed on the floor, the timbers of the head may not only be laid off, but the bevellings taken, and the very scores for the rails be cut out thus :

Take the heights in the sheer-plan, *fig. 1*, at the aft-side of each head-timber, from the upper side of the upper cheek to the upper and lower sides of each rail, for the outside of the rail, and set them up from the base line of their corresponding timber, *fig. 3*, striking the horizontal lines as there ticked. Then take the distances from the middle line in the half-breadth plan, *fig. 2*, at the aft-side of each timber to the outside of each rail, and set them off on their corresponding ticked lines, *fig. 3*. Where the aft-sides of the timbers, in the half-breadth plan, *fig. 2*, intersect the inside of the middle and lower rails, let them be drawn square from the lines N and O, to intersect the lines of the rails laid off. Then take the distances from the lines N and O, on the lines squared out, to the lines of the rails laid off, and set them down from the lines 33 and 34, at the aft-sides of their respective timbers in the sheer-plan, *fig. 1*, making spots which form the upper side of the rails at the inside, the same as was performed for the upper rail. Take the distances from the upper side of the cheek in the sheer-plan, *fig. 1*, at the aft-side of the timbers, to the spots last mentioned, and likewise to the line for the upper side of the upper rail at the inside, and set them up from the base line of each respective timber in *fig. 3*, and strike a faint line. Then take the distances from the middle line in the half-breadth plan, *fig. 2*, at the aft-side of each timber, to the inside of the before-mentioned rails, and set them off from the middle line *u*, in the plan of the timbers, *fig. 3*, on their corresponding faint lines. This gives the upper part of the rails at the inside. The same operation may be performed to find the lower part of the rails at the inside ; or you may draw the inside of the rails perpendicular, and set down the depth of the rails agreeable to what they measure on the moulds, taken in the direction of the timber. This may determine the under side of the rails at the inside.

As the line of the chamfer of the upper rail N (being the right-side of the rail when it is trimmed, and in its place) is before represented in the sheer-plan, *fig. 1*, take the height from the upper side of the cheek to the chamfer of the rail, at the aft-side of each timber, and set it up from the base line of each corresponding timber, *fig. 3*, striking faint lines parallel to the base line. Then take the half-breadths at the aft-side of each timber in the half-breadth plan, *fig. 2*, to the ticked line of the upper rail, (which is supposed to be where the rail is also to be chamfered,) and set them off from the middle line *u*, in *fig. 3*, on their corresponding lines last struck, and from thence draw the under side of the rail to the inside.

Having the upper side of all the rails, inside and outside, in the plan of the timbers, *fig. 3*, set off, draw the line for the upper side of the rails, which shews how much the inside of the rails is higher than the outside, if cut off in the direction of the aft-side of the timber. Then having the spots, as before mentioned, for the outside of the rails, (being on the ticked lines first drawn,) the under side of the rails may be drawn parallel to the upper, or to intersect the spot before-mentioned for the inside, which was set down agreeable to what it measures on the mould, taken in the direction of the rail, as it is marked on the mould.

Having the scores for the timbers, the half-thickness of the knee of the head at the aft-side of each timber, set it off from the middle line *u* on the base line of its corre-

sponding timber in *fig. 3*. Likewise take the height from the upper side of the upper cheek in the sheer-plan, *fig. 1*, to the ticked curve, representing the cutting-down or lacing of the knee, and set it up from the base line of each timber in *fig. 3*. This will give the score to be cut out, in order to let the timber meet its opposite at the middle line. Then set off the substance at the upper side of the upper cheek, and draw the inside and outside of the timber as represented in the plate. This will be the exact form of the timbers, or more particularly, of the scores of the middle rails ; and if laid off in the gross, might be performed to the greatest nicety.

*To bevel the Timbers in the Head.*—In the sheer-plan, *fig. 1*, set off the siding of the timbers, and strike in their fore-sides. Then square a line from the aft-side to the fore-side, from where the aft-side intersects the upper side of the cheek, as at 18, 19, 20, in the same manner as was done to find the bevellings of the cant-timbers.

Take the heights at the fore-side of each timber from its heel, as squared, to the upper and lower sides of the rails, in the same manner as directed for the aft-side, and set them up on the plan of each respective timber, *fig. 3* ; then set off the fore-side of each timber in the half-breadth plan, *fig. 2*, and take the distances from the middle line to the outside of each rail at the fore-side of each timber, and set them off on the plan of each respective timber, *fig. 3*, on their corresponding horizontal lines last mentioned. Where the fore-side of each timber in the half-breadth plan, *fig. 2*, intersects the inside of the middle and lower rails, let them be squared out from the lines N and O, to intersect the lines of their corresponding rails laid off. Then take the distances from the lines N and O, in the half-breadth plan, *fig. 2*, agreeable to the lines squared out, to the lines of the rails laid off, and set them down below their corresponding lines 33, 34, *fig. 1*, at the fore-side of each corresponding timber in the sheer-plan, *fig. 1*, making spots. Then take the heights from the square line at the heel up the fore-side of each timber in the sheer-plan, *fig. 1*, to the spots last mentioned, and set them up in the plan of their respective timbers, *fig. 3*, striking new horizontal lines. Then take the distances from the middle line in the half-breadth plan, *fig. 2*, at the fore-side of each timber to the inside of the rails, and set them off on their corresponding horizontal lines last struck, in the plan of each respective timber, *fig. 3*. This will give the direction of the upper side of the rails, and, if rightly performed, will be parallel to the upper side of the rails laid off for the aft-side.

In the same manner is every operation performed for the fore-side as was directed for the aft-side, the heights being taken from the heel as squared in the sheer-plan, *fig. 1*, instead of the upper side of the cheek, which shews how much the rails lift at the fore-side from a square ; and the half-breadths being taken at the fore-side of the timbers in the half-breadth plan, *fig. 2*, shew how much the scores at the fore-side of the timbers are under from a square with the aft-side, because the timbers in the half-breadth plan are square from the middle line.

Having the disposition of the rails for the fore-side of the timbers, set off the same distance from the rails as it is from the rails of the aft-side, both inside and outside, and mark the curves as ticked for the inside and outside of each timber, in the plan of the timbers, *fig. 3*. Then whatever distance the ticked lines of the fore-side are from the lines of the aft-side, so much is the outside of the timber under, and the inside standing from a square, agreeable to the siding of the timber. Or, having the aft-sides of the timbers laid off exactly, the fore and aft bevellings might be taken more cor-

## SHIP-BUILDING.

rect from the half-breadth plan, *fig. 2*. The bevelling for the heel of the timbers may be taken agreeable to the slight of the upper cheek, because the cheek stands fore and aft; but it will not answer exactly to the other bevellings agreeable to the slight of the rails in the sheer-plan, *fig. 1*, unless they are taken to the lines of the rails when laid off in the sheer-plan; and then the bevellings must be applied close to the scores that are trimmed for the cant of the rails.

*To Lay-off the Rails to the Cant in the Sheer-Plan.*—The perpendicular lines must be drawn in the sheer-plan, *fig. 1*, the same as before, and likewise those in the half-breadth plan, *fig. 2*, answerable to them. Let fall a perpendicular from the intersection of the upper part of the upper rail N, with the aft-side of the hair-bracket H, in the sheer-plan, *fig. 1*, down to the upper rail P, as before canted in the half-breadth plan, *fig. 2*, to which point the rail must be supposed fixed. Then place a batten to the inside of the rail, as canted in the half-breadth plan, *fig. 2*, and mark on the batten the perpendiculars as at 12, and the intersection of the lines 1, 2, 3, &c.

Then in the sheer-plan, *fig. 1*, where the perpendiculars 1, 2, 3, &c. intersect the upper side of the upper rail, level aft-lines at pleasure, as you there see ticked; then place the batten to each level line, marking thereon its corresponding perpendiculars, observing always to keep the foremost perpendicular marked on the batten to the perpendicular Y. This gives the spots to which a batten pinned will form the upper side of the upper rail O, and is exactly answerable in form to the upper side of the rail N, in the half-breadth plan, *fig. 2*. While the batten is pinned to the form of the rail, mark thereon the stations 1, 2, 3, &c.; and when it is straight, place it to any perpendicular line, and mark the extremities of the rail, and the several stations, as at 26, *fig. 1*; then set off the moulded size at each end, and strike a straight line, which will give the tapering at every perpendicular, and a batten pinned thereto will form the under side of the rail.

In the same manner are the other rails to be performed in the sheer-plan. The aft-side of the after-timber being already laid off, and the cant of the middle and lower rails being determined on the half-breadth plan, *fig. 2*; let fall the perpendiculars 35, 36, where the lines 33, 34, intersect the aft-part of the hair-bracket H, in the sheer-plan, *fig. 1*, down to the half-breadth plan, *fig. 2*, and proceed as above.

It may be necessary to notice here, that when *Plate I.* was engraved, all vessels above a frigate in the royal navy had beak-heads, which mode has lately been discontinued: but such of our readers as may be desirous of knowing the best method of laying-off the beak-head timbers, are referred to the “*Elements and Practice of Naval Architecture*,” by Steel.

### *To Lay-off the several Parts of the Stern.*

*To Lay-off the Side Stern-Timber.*—The side stern-timber must be laid off on the floor, and a mould made to it, so that when trimmed and put up in its place on the ship, that is, to the tumbling-home of the side, it should appear as its ticked line in the sheer-plan, *Plate I.* from whence it is transferred to the floor.

Strike the horizontal lines from the stern-timber in the sheer-plan, *Plate VII. fig. 11. Laying-off A*, to square-timber 35, at the wing-transom, at the side, at the knuckles of the upper and lower counters, at the top-breadth, and at the top-side. Likewise strike as many between the wing-transom and lower counter as may be thought necessary, that part being the most critical to obtain the exact form

of the timber. Then transfer these horizontal lines to the after-body plan, *fig. 5*, as you see ticked in the plate, and number them accordingly. Then take off the half-breadth of each horizontal line in the body-plan, *fig. 5*, at every square timber, as far forward as timber 28, and transfer them to their corresponding square timbers in the half-breadth plan, *fig. 6*. To these spots pin a batten, and mark the curves, or half-breadths, and continue them as far aft as the stern-timber in the sheer-plan, *fig. 11*, and number them in the half-breadth plan, *fig. 6*, as in the plate.

Where the horizontal lines in the sheer-plan, *fig. 11*, intersect the aft-part of the stern-timber, square them down, or let fall perpendiculars to their corresponding lines in the half-breadth plan, *fig. 6*, as shewn in the plate. This gives the ending of the after-part of the half-breadth lines. Then take off the half-breadths of the horizontal lines in the half-breadth plan, *fig. 6*, at their ending, as above-mentioned, and set them off on their corresponding horizontal lines in the body-plan, *fig. 5*. A batten pinned to those spots forms the aft-side of the stern-timber A, agreeable to the form in the sheer-plan. But if these half-breadths, when set off in the body-plan, should not make a fair line, then those in the half-breadth plan, *fig. 6*, which seem most to require it, must be altered at the after-end, till they all correspond to make a fair line in the body-plan.

Now set off the moulded size of the stern-timber upon each horizontal line, in *fig. 11*, to which pin a batten, and the fore-side of the timber will be represented, because the mould is to be made broad enough to be answerable to the fore-side of the timber.

Then, where the horizontal lines in the sheer-plan, *fig. 11*, intersect the fore-side of the timber, transfer them to their corresponding lines in the half-breadth plan, *fig. 6*, parallel to the other lines, which are ticked down from the aft-side, and on the half-breadth lines make the spots as you see in the plate. Then take the half-breadth of each horizontal line in the half-breadth plan, *fig. 6*, at the spots last-mentioned, and set them off on their corresponding horizontal lines in the body-plan, *fig. 5*. Pin a batten to these spots, and mark the line B, which is the fore-side of the timber, agreeable to the line for the fore-side in the sheer-plan.

Having in the body-plan, *fig. 11*, the form of the aft-side and fore-side of the stern-timber, as it appears upon an horizontal view when in its place, it follows next to point out a method to make a mould, in order to mould the timber, so that it shall have the same appearance when it is in its place upon a horizontal view, as it now shews in the sheer and body-plans. Unless there be a method which may be depended upon for the exact heights of the counters, it can be to no purpose to design a view of the stern, in order to dispose of the decks, the lights, and all other heights, in such a manner, that each part may bear a just proportion to the rest.

Strike the line C in the body-plan, *fig. 11*, the thickness of the mould from the side of the timber, to which place a batten, and keep one end well with the horizontal line at the end of the wing-transom, and mark on the batten all the horizontal lines in the body-plan. Then carry the batten to the sheer-plan, *fig. 11*, and keeping the end of the batten well with the horizontal line A of the wing-transom at the side, set up all the heights on the batten perpendicular, and strike them through the stern-timber parallel to the horizontal lines first struck, as you see in the plate. Where the ticked horizontal lines in the sheer-plan, *fig. 11*, first struck intersect the fore-side and aft-side of the stern-timber, square them up to the horizontal lines last struck. This will give the spots, to which a batten pinned will give the ticked

## SHIP-BUILDING.

ticked lines I and H, to which the mould is to be made. The last heights which were set up are the proper heights of the knuckles and horizontal lines to be marked on the mould.

The ticked lines I, H, in the sheer-plan, *fig. 11*, to which the mould is to be made, are supposed to be the straight line C in the body-plan, *fig. 11*, standing falt at the wing-transom, and the head lifted up till it stands perpendicular; which, if lowered again to the direction of the straight line C, in the body-plan, *fig. 11*, will appear exactly the same as the stern-timber first laid off in the sheer-plan, *fig. 11*, which is the form of the timber required when trimmed and in its place.

In the next place, the mould should be so made, that the stern-timber shall be trimmed both ways by this one mould; that is, to the shape as it appears in the sheer-plan, *fig. 11*; and likewise to the fore-side and aft-side thwartship appearance in the body-plan, *fig. 11*.

Proceed to make the mould of dry seasoned inch-deal to the ticked lines I, H, *fig. 11*, in the sheer-plan, from the upper side of the wing-transom at the side to the head G; then, when the mould is in its place, mark on it the upper horizontal lines, in the same direction as they are laid off, distinguishing them by their proper names on the mould, as the lower counter at D, upper counter at E, heel at A, No. 1 at B, No. 2 at C, No. 5 at F, and head at G. Then take the distances from the straight line C, in the body-plan, *fig. 11*, to the fore-side of the stern-timber B, at every horizontal line, and in the direction of the horizontal lines, and set them down in figures at the fore-side of the mould on their corresponding horizontal lines: then proceed in the same manner, and set down the distances or spilings on the aft-side of the mould from the lines C and A. But to mould the timber from those spilings requires much trouble, and without great care taken, the stern-timber will not be exactly moulded.

Therefore, the most correct method of finishing the mould, and the easiest in application when moulding the piece, is, instead of having the spilings marked on the mould, to have brackets made of  $\frac{3}{4}$ -inch deal, agreeable to the spilings (deducting the thickness of the mould) at each horizontal line, having their ends at the fore-side and aft-side cut exactly square from the mould, or their aft-sides may reach to the round-aft; then fasten those brackets to the under side of the mould, keeping the middle of their thickness exactly well with their respective horizontal lines, as they appear shaded in the sheer-plan, *fig. 11*, observing to keep the side of every bracket in the same direction from the mould as the bevel at F, *fig. 11*, in the body-plan, that is, to the inclination which the straight line C has from an horizontal plane in representing the tumbling-home of the stern-timber.

To be more exact, let the half-thickness of the brackets be gauged down to their ends, and the sides chamfered away thereto, which will direct upon the timber, when trimmed, the exact stations of the knuckles, and also of the horizontal lines.

The brackets may be so fixed on either side, as to mould the timber for both sides of the ship.

The mould, thus made, may be applied in any direction in moulding the timber, provided its upper side is kept straight, and out of winding. Then examine where the timber, in its rough state, deviates most from the under side of the brackets, and make that the general spiling to be applied from the under side of the brackets. Wherever this spiling must be applied beyond the brackets, owing to the inequalities of the piece, let a straight-edged batten, of suf-

ficient length, be kept well to the under side of the bracket; from which set down the spiling required, wherever it may touch the piece. Then by boring holes with a small gimblet, exactly in the direction of the gauge-line, at the ends of the brackets, and full as much below the brackets as the general spiling, you will preserve the exact moulding of the timber, after the rough wood is sawn off, agreeable to the mould.

To take the bevellings of the aft-side of the timber, the round-aft of the stern at the counters, and top-timber line, must be laid off thus in the half-breadth plan. Take the distance from the midship to the side stern-timber, on a square in the sheer-plan, *Plate I.*, and set it off upon the middle line, *Plate VII. fig. 6*, abast its corresponding perpendicular, as squared down from the counters, &c. at the side, sweeping curves to the said round-aft on a square; then fix the tongue of a bevel to the different round-aft lines, and the stock parallel to the middle line will be the bevelling of the round-aft at each place, to be applied square from the mould.

Take the bevelling to cut off the heel from the body-plan, *Plate VII. fig. 11*, thus: fix the stock of a bevel to the line C, and the tongue to the round-up of the wing-transom, as at D; and apply it over the heel of the mould, when it lies in its proper place, to where the lower bracket strikes the timber.

Supposing the heel of the timber to be carefully trimmed, as above directed, a thin mould may be made to the section of the heel on the wing-transom, and the bevellings taken to lay it to the fashion-piece from the stern-frame, as that is generally in its place before the stern-timbers are trimmed.

The bevellings for the round-up of the knuckles of the lower and upper counters may be taken from the body-plan, *Plate VII. fig. 11*, by fixing the stock of a bevel to the aft-side of stern-timber A, and the tongue to the round-up, as at E, and so applied from the timber when it is trimmed.

### *To Lay-off the Stern and Quarter-Galleries, Plate X. Laying off D.*

In *Plate VII. Laying-off A*, the laying-off of the side stern-timber to make the mould to, is represented in its proper situation, that the reader might have a clearer idea of the operation. But we are not to suppose that any mould-loft is broad enough to admit of the stern to be laid off in that manner; neither would it appear clear enough, if laid off in the body-plan.

Therefore, in some convenient part of the floor, lay off the horizontal (or level) view of the stern, as *Plate X. fig. 6*, from *Plate I.*; and likewise the quarter, as far forward as timber 32, as *fig. 4*.

Strike an horizontal line at the upper side of the wing-transom at the middle line, which will be a base line to the stern; likewise the lines 17 and 18 parallel to the base line, to intersect the knuckles of the lower and upper counters, at the side stern-timber 33, in *fig. 4*; continuing them through their respective timbers in *fig. 6*. Then take the heights from the base line, in *fig. 4*, to the knuckles of the lower and upper counters at the midship stern-timber 32, and set them up the middle line above the base line, in *fig. 6*. Then spring the arc of a circle through those heights in *fig. 6*, and as far as the quarters project, as B, B, which will be the knuckles of the timbers. Design the lower and upper counter-rails in *fig. 4*, and set off the projection of the plank of each counter, thus: square out a line from the knuckle of each counter of the midship-timber 32, as *a* and *b*, and draw the thickness of the plank of each counter

## SHIP-BUILDING.

parallel to the timber, which gives the under side of the rails; then transfer the upper and under sides of those rails from *fig. 4*, to the middle line, *fig. 6*, and describe parallel curves to the knuckles 42 and 43; and the upper counter-rail B, and lower counter-rail A, will be also represented in the plan of the stern, *fig. 6*, and that will shew how much the sight-part of the rails will be on a level view below the knuckles of the timbers.

But the round-up and round-aft of the counter-rails, to make the moulds to for trimming the rails, must be laid off on a square, thus: from the fore-side of the rails at the midship-timber 34, in *fig. 4*, square in a line from the knuckle to touch the side-timber 33; then take the distance from the knuckle of the upper counter from the midship-timber 32, to the side-timber 33, in the direction of the above square line, and set it off from any straight line, as AA, at CC, *fig. 9*, which is the knuckle or breadth of the upper counter, squared down from *fig. 6*. Then spring the arc BB, which is the round-aft of the upper counter, on a square.

Next take the distance from the knuckle of the upper counter, at the side-timber 33, to the line squared in from the knuckle of the midship-timber, and set it off as before at CC, above the line AA, *fig. 9*, and spring another arc, which will be the round-up of the upper counter, on a square. Proceed in the same manner with the lower counter, and we shall have both rails laid off to the round-up and round-aft on a square.

This is the best way to make the moulds for the round of the rails; because if the rails were cut out of a flying plank, or piece of thick-stuff, the round-up would be the same; that when put in the boiler, and set to the round-aft, they would then have their proper round-up on a level view; or, were they cut out of a small piece of timber, it would answer the same purpose, and be most expeditious and exact.

The counter-rails may be cut out of a straight piece of timber, without kilning them, as they are apt to fly after that process, thus: take the round-up and round-aft together, that is, from the knuckle of the side-timber to the knuckle of the midship-timber, and spring an arc thereto, as before; then when the rails are trimmed to the sheer, and the fore-side canted to the timber, they will exactly conform to the round-up and round-aft, when put in their places.

Having the round-up of the lower and upper counter-rails in *fig. 6*, and continued them far enough out for the projection of the quarter-galleries, round up the quarter-deck in the stern, agreeable to the upper counter-rail, in the following manner: take the height from the upper counter-rail, in *fig. 6*, to the quarter-deck, in the direction of the side-timber at the inside; and set it up the middle line of the stern. This makes the quarter-deck round more than the upper counter-rail, and adds life to the stern; for the upper part of the lights in the stern should be parallel to the transom. And if they were to round by the same mould as the upper counter-rail, the bars in the falhes next the side would be longer than those in the middle line, and would appear as if the top of the lights rounded less than the upper counter-rail. In the same manner dispose of the round of the poop, or round-house.

This should determine the round of the decks abaft; and the beams of those decks, as they approach aft in *fig. 4*, must be gradually increased in their round-up, to correspond with the transom.

Observe that the above lines, in *fig. 6*, for the quarter-deck, shew the round of the deck at the stern-timbers,

without considering at present the projection of the balcony.

Set off withinside of the stern-timber, in *fig. 6*, the thickness of the clamp, and the projection of the cornice in the cabin, and let that be the side of the light. Then determine on the breadth of the munions, allowing sufficient for the weights and pulley-pieces, and divide the other lights equally. Set off likewise the mock-light in the aft-part of the quarter-gallery, the same size as the rest. About half the breadth of the munions from the mock-light, place the inside of the quarter-piece; then determine on the breadth of the quarter-piece at the heel. About the middle of the quarter-piece place the outside of the gallery, which determines the outside of the gallery on the quarters, *fig. 4*. Having the breadth of the lower part of the lights in the clear, let the depth be one-third more than the breadth at the lower part; set off upon the rake of the stern-timbers, in *fig. 4*, and transfer that to *fig. 6*, which makes a good proportional light. But observe, between the upper counter-rail and the lights must be room allowed for the fast-fills, and about one inch and a half between their heads and the transom above. Then determine on the out-bounds of the taffrail and quarter-pieces, and lower finishing.

Next dispose of the quarter-gallery in *fig. 4*, shewing the out-lines of the quarter-piece and taffrail, thus: let fall a perpendicular from the knuckles of the lower and upper counters of the midship-timbers, in *fig. 4*, as you see ticked and numbered 14 and 15; then where the horizontal lines 17 and 18, from the knuckles of the side-timber, intersect the perpendiculars 14 and 15, take those distances, and set them off from the knuckles of the side-timber, in *fig. 6*, down the perpendiculars, *c, c, f, f*; from thence spring the arcs 24, 24, and 26, 26, to touch the horizontal lines 17 and 18, at the middle line, which are called *round forward on a level*. Then will the ticked curves 24, 24, and 26, 26, be answerable to the ticked perpendiculars 14, 15, which fall from the knuckles of the midship-timber in *fig. 4*.

Take the heights from the base-line, in *fig. 6*, to the knuckles of each counter, at the outside of the gallery, at the ticked perpendiculars *d* and *e*, and set them up from the base line in *fig. 4*, striking the ticked horizontal lines *c* and *d*. Then from the horizontal ticked lines 17 and 18, in *fig. 6*, take the length of the perpendiculars *d* and *e*, to where they intersect the ticked curves 24 and 26, or round forward on a level, and set them off forward from the perpendiculars 14 and 15, in *fig. 4*, on the horizontal lines *c* and *d* respectively, which will give the exact knuckles at the timbers, in *fig. 4*, at the outside of the gallery. Then take the heights of the ends of the rails from the base line at A and B, *fig. 6*, and set them off from the base line in *fig. 4*, at the knuckles of the timbers last mentioned, and continue them forward, agreeable to the sheer of the ship. This will give the exact heights of the lower and second counter-rails, as they will appear on the ship, if the work be conformable to the floor.

### *To Lay-off the Foot-Rail of the Balcony.*

Here we may again repeat the observation, which was made about laying-off the beak-head timber, that since *Plate I.* was engraved, the sterns of all ships of the line are now continued upwards to the round-aft of the second counter-rail, without any balcony, as they are much stronger so, and more useful, if guns are wanted to be used right-aft occasionally. Nevertheless, ships of 50 guns have at present a balcony or walk in the stern.

To understand the exact form of the balcony-rails, as they appear in the sheer-plan, and likewise in the plan of the stern,

## SHIP-BUILDING.

stern, will require much attention, and some pains taken to be made correct.

Where the quarter-deck line at the side intersects the side-stern timber 33, in *fig. 4*, let fall the ticked perpendicular 13 to the half-breadth plan, *fig. 5*; and on that perpendicular set off the half-breadth of the quarter-deck at the stern-timber, from the middle line in *fig. 5*, as taken from *fig. 6*. Then square down from the last perpendicular, where the under side of the deck at the middle line intersects the midship-stern timber, in *fig. 4*, to the middle line in *fig. 5*; and spring an arc, as the ticked curve I, shewing the round-aft of the stern, at the under side of the quarter-deck, and also at the aft-part of the timbers, the heads of which run up to the under side of the quarter-deck. But sterns having no balcony, the timbers are continued upwards as much above the taffrail as they may be wanted, which certainly must add strength to the stern.

In *fig. 5*, draw the side stern-timber, which requires to project aft, about ten inches farther than the midship-timbers, as at 24, for the convenience of the necessaries in the quarter-gallery, and abaft that allow three or four inches for the ballusters in the aft part of the quarter-gallery, and let that be the aft part of the quarter-deck at the side. Then design, in *fig. 5*, the midship part of the ends of the deck. That part, from the side-timber to the outside of the gallery, (being the aft part of the stool,) must be parallel to the ticked line I.

Strike the perpendicular line 43 abaft *figs. 4* and *5*, and where the ticked line I, which is the round-aft at the heads of the timbers in *fig. 5*, intersects the outside of the timber, take that half-breadth, and set it off on the perpendicular 43 from the middle line. Then take the round-up of the quarter-deck on a perpendicular, in *fig. 4*, at the side-timber, and set it off on the half-breadth last taken from the perpendicular 43, and spring the arc H, which is the round-up of the quarter-deck, on a perpendicular.

Let the quarter-deck, at the middle line in *fig. 4*, be continued as far aft as the ends of the deck *c*, in *fig. 5*; then from the line for the under side of the deck, drop as many perpendiculars as may be thought sufficient to find the true form of the under side of the deck, from the side to the midships, as may be seen numbered 23, &c. in *fig. 4*. Carry down those perpendiculars parallel to the line 43, to intersect the ends of the deck *c*, in *fig. 5*, and from thence carry them aft parallel to the middle line, to intersect the round-up of the deck H. Then take the distance from the line 43, to the curve H, for the round of the deck at 14, *fig. 5*; and set it down the perpendicular 3, from the under side of the deck, *fig. 4*. (for *per. 2* was too small a round to be perceived in the plate); continue the same regular to 20, *fig. 5*, which answers to *per. 9*, in *fig. 4*. Take the half-breadth in *fig. 6*, to the outside of the quarter-deck stool, and set it off square from the middle line to intersect the ends of the deck *c*, in *fig. 5*. Then carry aft, as before, to the curve H, the intermediate lines 21, 22, with 23, at the outside of the stool, and also carry them up to the under side of the deck in *fig. 4*, as 10, 11, 12. Then take the distances from the line 43 to the round of the deck H, in *fig. 5*, at 21, 22, 23, and let them off below the under side of the deck, on the perpendiculars 10, 11, 12. Then through these spots, and those before set off, draw the ticked curve to the aft part of the quarter-deck at the middle line. This will be the exact form of the under side of the quarter-deck, if cut off agreeable to the plan, *fig. 5*, from the outside of the stool in *fig. 4*. Draw the ticked line 40, in *fig. 4*, agreeable to the sheer of the ship, and set off below the line 40 about one inch and a half, or as

much as the joiners require for the pannelling which is at the under side of the balcony, and from that set up the depth of the rail. This will give the exact height of the foot-rail in the sheer, *fig. 4*.

To find the proper height of the aft part of the quarter-deck at the under side, answerable to that in the sheer, *fig. 4*, take the half-breadths at the ticked lines 14 to 23, on the line 43, in *fig. 5*, and set them off from the middle line on the base line, as on the left-hand, in *fig. 6*, and erect perpendiculars as high as the under side of the deck. Then take the heights from the base line, in *fig. 4*, to the under side of the deck, at Nos. 2, 3, &c. and set them up on their corresponding perpendiculars in *fig. 6*. Through these spots get in a ticked line, which will give the under side of the deck in *fig. 6*; then set off the thickness of the deck, and get in the parallel line above it. Likewise set off the foot-rail, as before directed, in *fig. 4*. This will give the exact form of the foot-rail, in *fig. 6*, agreeable to the round-aft in the plan of the quarter-deck, *fig. 5*.

### *To Lay-off the Breast-Rail of the Balcony.*

It has been customary to mould the breast-rail of the balcony with the same mould as the foot-space-rail is done with. But to complete the range of ballusters in the balcony, so as to make them have an agreeable rake in the sheer, *fig. 4*, and likewise a proper diminish of tumbling-home in the plan of the stern, *fig. 6*, the following method only can be relied on.

In the plan of the stern, *fig. 6*, let the side-timber be produced upwards till it intersects the middle line; and from that point to the above-mentioned stations at the under side of the quarter-deck, in *fig. 6*, make ticked lines as high as the breast-rail. Whatever height the upper side of the breast-rail is intended to be at the middle line, in *fig. 6*, take that height from the deck at the middle line, and set it up from the deck at the several ticked lines in the direction of the said lines, as well as at the side-timber. Through these spots get in the upper side of the breast-rail D, in *fig. 6*. Supposing these ticked lines to be ballusters, they should all be of an equal length. Where the perpendicular ticked lines 2, 3, &c. in *fig. 4*, intersect the ticked line for the deck at the side, draw them upwards parallel to the side stern-timber; then take perpendicularly the heights of each of the ticked lines at the upper side of the breast-rail from the base line in *fig. 6*, and set them, as taken from the base line, *fig. 4*, to intersect their corresponding lines last-mentioned. Through these spots draw the curve K, which is the upper side of the breast-rail, as it will appear in the sheer, *fig. 4*.

Drop the ticked perpendicular 1, from the aft-side of the breast-rail, *fig. 4*, to the middle line, *fig. 5*, and parallel to that the ticked perpendiculars 2 to 11, which will be found to intersect the ticked lines at the upper side of the breast-rail in *fig. 4*. Then take the distances (or half-breadths) from the ticked lines afore-mentioned at the upper side of the breast-rail in *fig. 6*, to the middle line; and set them off on their corresponding perpendiculars 2, 3, &c. from the middle line in *fig. 5*; a batten pinned through these half-breadths forms the line G, or upper side of the breast-rail. But observe, it only gives the form of the breast-rail corresponding with the aft part of the deck *c*; therefore, if the ballusters are laid off in this manner, the fore-side of the mould is the reader to apply on the deck, in order to cut off the deals, and what the rail is intended to rebate on the ends of the deals must be added thereto, and as much wood as is necessary to raise the members of the rail must be left on the mould abaft the

line *c*.

line *c*. Whatever is left abaft the foot-rail mould must be also left abaft the line *G* for the mould of the breast-rail, upon a supposition that both moulds are made to suit the aft part of the ballusters. The half-breadth of the rails only being laid off is the most correct, for then the moulds will be made in two halves exactly alike, and may be scarfed and nailed together in the middle from any straight line. The middle line and outside of the timber should be marked on each mould.

*To Lay-off the Taffrail and Quarter-Piece.*

The form of the taffrail and quarter-piece, in *fig. 6*, being laid off from the plan of the stern, *Plate I.*, square up from *fig. 5*. what the stern projects at 24, to the quarter-deck in *fig. 4*, and continue it upwards parallel to the side stern-timber to the top of the side, as you see ticked; then set off the half-breadth of the stern at the quarter-deck, and likewise at the top of the side on the ticked line 25, *fig. 6*, taking the round-aft at each place, and set it aft at the corresponding heights from the above ticked line in *fig. 4*. This will give the ticked line *T*, being the midship-timber at the upper part of the stern, or the fore-side of the taffrail at the middle line. Let this ticked line *T* be answerable to the line *AA*, *fig. 9*.

Drop as many perpendiculars from the top of the taffrail and outside of the quarter-piece, as in the left-hand of *fig. 6*, as may be thought necessary. Take the perpendicular heights from the base line in *fig. 6*, to the several perpendiculars last mentioned on the taffrail and quarter-piece, and set them up from the base line in *fig. 4*, and strike in the horizontal lines 22 to 31, the last being the height of the taffrail at the middle line. Take square from the middle line in *fig. 6*, where each perpendicular intersects the upper part of the taffrail and outside of the quarter-piece, and set them off from the middle line on the ticked line 25, *fig. 6*; then take the distances from the ticked line 25, to the round of the stern on a level 26, 26, at each line squared down, and set them off on their corresponding lines last struck in *fig. 4*, from the ticked line *T*, forward in the direction of the ticked lines. A batten pinned to those spots will give the ticked curve *Q* in the middle of the quarter-piece (which, in a thwartship view, is the aft-part of the timbers, supposed to be continued to the heel of the quarter-piece); then abaft this ticked line set off the aft-side of the taffrail, and continue it to the heel of the quarter-piece; that will determine the aft-side of the quarter-piece, from which set forward the siding of the quarter-piece, and that gives its fore-side, as it will appear when in its place.

The rims and stools might be all laid off on the floor; but it would appear confused on the plate, and perplex the reader. And, indeed, the making of a handsome quarter-gallery depends chiefly on the performance on the ship; therefore an explanation may give more useful information than a drawing.

The length of the rims and stools being determined in *fig. 4*, the breadth abaft need only be taken from *fig. 6*, and let the stool at the quarter-deck serve for all the rims and stools in the quarter-gallery, keeping the foremost end well. At least, the same mould that moulds the stool at the upper parts of the lights, may mould the rim at the lower part of the same lights, because the munions in the quarter-gallery should be all out of winding; and in order to make them so, the stool at the quarter-deck will require to be longer than the rim at the lower part of the lights, more or less, according to the winding of the top-side. This might be allowed for exactly in laying-off the stools;

but it is better to leave the stool at the quarter-deck long enough, and proceed in the following manner.

Suppose the rim at the second counter-rail to be trimmed agreeable to the form of the stool at the quarter-deck, and to be in its place on the ship; and suppose the stool at the quarter-deck to be fayd to the side: then set off the breadth of the stool at the aft part, and nail a batten from thence to the rim. Then set off the munions on the rim, and at every munion on the rim hold a straight batten from thence to the under side of the stool, and look them out of winding with the batten at the aft part, or with each other, observing to set off the same distances at the under side of the stool from the aft part as they are on the rim. Then the wood may be dubbed away, or the stool taken down, and mould the under side (which will nearly agree) to every spot, with the same mould as the rim was moulded with. Then you may be certain the fashes will be out of winding, and, if required, would slide from one end of the gallery to the other. Then, when the munions are set off, you may find a greater distance from the foremost munion to the side on the stool, than there will be on the rim; but this cannot be avoided, and is of but little consequence; because the canting-livre, or console-bracket, is introduced on purpose to intercept the finishing of the gallery with the ship-side: for if the stool at the quarter-deck was to be no longer than the rim at the second counter, it would fall into the hollow of the top-side at the foremost end, and the foremost munions in the view of the sheer, *fig. 4*, would appear to rake more than the after ones; and when looking from before the gallery, the munions in the lower and upper gallery would not appear out of winding, but the whole gallery would seem in confusion; therefore the upper gallery must undergo the same operation, and then it will bear to be viewed in any direction.

It is requisite, at least, to lay off the stool and rim of the lower gallery, and allow for the winding of the top-side, in order to mould them nearly; but by following the above method in the performance of the work, any little error that may happen will be corrected.

To lay off the lower rim *B*, and middle stool *c*, *fig. 4*, to make the moulds to, transfer the height of the upper side of the lower rim *B*, and upper stool *c*, in *fig. 4*, continued forward to square timber 32, to the body-plan, *Plate VII. fig. 5*, upon its corresponding square timbers. Then take the half-breadths as far forward as square timber 32, and set them off from the middle line on their corresponding timbers in *Plate X. fig. 5*, and produce the half-breadth lines, and thickness of the planks *A* and *B* without it, as far aft as in the plan, *fig. 5*.

Then square down the knuckles of the upper counter from *fig. 4* to *fig. 5*, and spring an arc to the round-aft, which will be the fore-side of the upper counter-rail. Next sweep another arc to the thickness of the upper counter-rail, parallel to and abaft the ticked curve, and the upper counter-rail will be shewn in the plan, *fig. 5*. Then take the half-breadth of the upper side of the upper counter-rail to the outside, *B*, in *fig. 6*, and set it off from the middle line in *fig. 5*, on the ticked perpendicular 13, as squared down from the outside knuckle. Thence form the curve *F*, or outside of the lower rim. The ticked parallel line within is the outside of the munions, upon which set off the stations of the lights, making them all alike, and the munions 44, 45, 46, 47, between. Square up the munions to the upper side of the lower rim in *fig. 4*; and from the spots squared up strike lines parallel to the side stern-timber, to the under side of the middle stool. The aft part of the middle stool is already laid off in *fig. 5*, and the form of the outside may

## SHIP-BUILDING.

be determined by the inside of the mould of the lower rim keeping the fore end well, and allowing the additional length required by the winding of the top-side, &c. Then to prove that the outer edge of the rim and stool are out of winding, square down the sides of the munions from the under side of the middle stool in *fig. 4*, to the outside of the middle stool in *fig. 5*; and at the aft-sides of the munions, take their half-breadths from the middle line, and set them off square from the middle line in *fig. 6*, upon the under side of the middle stool. In the same manner take off the half-breadths of the munions on the rim, and set them off on the upper side of the upper counter-rail. Then strike lines to those spots in *fig. 6*, and they will be parallel to the side stern-timber and each other, consequently out of winding. The upper gallery rim and stools may be laid off in the same manner, and the moulds also made; observing to rake the munions of the upper lights agreeably to those below, which may be set off as follows. Determine on the fore-part of the upper gallery, and continue it upwards as the ticked line H, in *fig. 4*; then with a batten, fitted as square as possible from the fore-side of the foremost munion, mark on it the sides of all the munions. Then fit the same end of the batten to the ticked line H, and move it diagonally, till the aft-side of the after-munion touches the fore-side of the quarter-piece, and mark all the sides of the munion as on the ticked line 41; then striking lines through those spots parallel to the rake of the lower munions, the lights and munions will be represented in the upper gallery.

The upper and lower finishings may be formed at pleasure, making them as light as possible, to please the eye, and containing sufficient room in the upper finishing to hold a cistern.

### *To Lay-off the Stern upon the Rake.*

The horizontal plan of the stern being laid off, proceed to lay off the stern upon the rake; or, at least, the taffrail and quarter-pieces. For, were moulds made to them as already laid off, it is easy to conceive that they would be too low and too narrow, when fixed upon the stern, to its round-aft and rake; which must be the case upon the ship. In the plan of the stern, *fig. 6*, strike up lines in the middle of each munion, one in the middle of the side stern-timber, one up the inside of the quarter-piece, and one between, to rake upwards to the centre of the stern, at the middle line, as marked 35, 36, 37, and 38, as on the right hand.

Draw the horizontal line B B through *figs. 7* and *8*, which will correspond with the ticked lines 25, 25, at the upper counter in *fig. 6*. Take the perpendicular heights of all the timbers, from 35 to 38, and at the inside of the quarter-piece in *fig. 6*, from the lines 25, 25, to the ticked curve for the knuckles of the upper counter, and set them up from the line B B in *fig. 8*, and draw parallel lines thereto, as you see ticked, and numbered 9, 10, &c. Take likewise the perpendicular heights from the lines 25, 25, *fig. 6*, to the intersections of all the timbers, with the under and upper sides of the taffrail and quarter-piece; and set them up from the line B B, in *fig. 8*, where they are ticked and numbered as before.

Strike lines to the rake of the midship and side counter-timbers above the upper counter-rail, taken from *fig. 4*, and transferred to *fig. 8*, as the ticked lines 32 and 33. Draw a line square from the midship stern-timber 33, in *fig. 8*, to intersect the knuckle at the upper counter at the side-timber, as the ticked line 30; then continue the midship-timber 32 down to the line 30; then take the distance from the midship to the side-timber in the direction of the ticked line 30, and set it off from the line A A, in *fig. 9*, on the ticked

lines C, C, and raise the arc B B, which shews how much the stern rounds aft on a square, agreeable to the breadth of the upper counter, which round-aft governs all the stern above, as before observed.

Where the timbers 35, 36, 37, 38, and inside of the quarter-piece, *fig. 6*, step on the ticked line 42, or knuckles of the upper counter, square them down to *fig. 9*; then take the round-aft of each timber from the line A A, *fig. 9*, and set them off square from the midship-timber 32, so as to intersect their corresponding level lines in *fig. 8*. Then where the above timbers in *fig. 6*, intersect the upper part of the taffrail and quarter-piece, let them be squared down as before; and transfer the round-afts to their corresponding level lines in *fig. 8*, setting them off square from the midship-timber, as before. Then from these spots, down to the spots on the level lines of the knuckle of the upper counter, strike the lines of the intermediate timbers, and mark them 1, 2, 3, &c. which shews the thwartship view of the timbers, as stationed in *fig. 6*.

If the side-timber 33, and midship-timber 32, were prolonged in *fig. 8*, till they intersect each other, that would be the centre for the intermediate timbers, as disposed in *fig. 6*, and prove the work.

It will be necessary to have one spot at the outside of the quarter-piece, as 39, *fig. 6*, and squared down, as before, to the round-aft, *fig. 9*; then take its round-aft at 11, *fig. 9*, from the line A A, and set it off square from the midship-timber 32, in *fig. 8*, on its corresponding level line 16, as transferred from *fig. 6*.

Square down the heel of the quarter-piece where it intersects the knuckle-line, 42, *fig. 6*, to *fig. 9*, to the round-aft B B. Then pin a batten to the round-aft on a square B B, *fig. 9*, and keeping it fast at the middle line, mark spots on the batten, where the ticked lines 2, 4, 7, 10, 12, and outside of quarter-piece, are squared down from the knuckle-line 42, *fig. 6*. Then fit the same end of the batten well to the middle line, *fig. 7*, keeping it straight along the line B, and thereon mark the several spots on the right hand, and likewise on the left. Then, if the floor will admit of it, continue upwards the spots in the middle of the side counter-timber, as at 13, 13, *fig. 7*, till they intersect the middle line, and from thence, as a centre, may all the other spots be continued upwards, as in the plate. But if this cannot be performed, the heights of the timbers 35, 36, &c. must be taken up their perpendicular lines, from the line 25, 25, *fig. 6*, to where they intersect the upper side of the taffrail and quarter-pieces, and set up from its corresponding line 25 the middle line in *fig. 7*, striking horizontal lines; then pin a batten, as above, to the round-aft B B, *fig. 9*, and mark spots thereon at the middle line, and perpendicular lines 1, 2, 3, 5, &c. squared down from their heads; and set them off upon their corresponding heights last set off in *fig. 7*; then lines struck through those spots to the spots before set off on the line 25, or B B, the timbers will have their regular tumble-home, as from the centre in the plate. Then take the distance square from the line 30 in *fig. 8*, up each separate timber, to the spots on the level lines for the upper part of the taffrail and quarter-pieces; and set them up square from the line B B, *fig. 7*, to intersect their respective timbers, and in like manner the spot at the outside of the quarter-piece; then a batten pinned to those spots will represent the boundary of the stern or taffrail T, and quarter-pieces Q, Q, on the rake, *fig. 7*. Then take the heights square from the line 30, *fig. 8*, up the separate timbers, to the heights for the lower part of the taffrail and inside of the quarter-pieces, and set them up, as before, on their corresponding timbers in *fig. 7*; then by pinning a batten

## SHIP-BUILDING.

batten to those spots, the under side of the taffrail I, and inside of the quarter-pieces, will be completed to make the moulds to. The cove-rail D may be also marked on the taffrail mould, and likewise upon the quarter-piece mould.

### *Practical Directions for the actual Building.*

Having now explained the usual methods of forming the draughts, and laying off the several parts of the ship, it remains only to describe the progressive manner of its actual building, or putting together the several parts.

A slip being provided, the blocks on which the keel is laid are usually about five feet asunder. Each block is laid upon a ground-way in the middle of the slip, unless a smaller vessel is intended to be built where the launch has been laid for a large ship. In this case, by keeping the blocks towards one side, the sliding-planks may be preferred for that side.

The blocks, being the foundation of the whole, must be very carefully fixed, and their upper surface to a declivity of five-eighths of an inch to every foot in the length, observing that there may be water enough to launch the ship into, and keeping them high enough at the fore-part to clear the fore-foot of the ground-ways in launching, and to admit of the sliding-planks to be laid with a declivity of about seven-eighths of an inch to a foot.

The caps or upper blocks should be more in depth than the false keel; and they should be clear-grained oak, that they may split out the easier when the false keel is put under.

The upper sides of the blocks are made straight fore and aft, and level athwartships; sometimes the after-blocks are raised above a straight line, as the great weight of the stern and overhanging generally settle in building.

*Keel* is generally elm, sawn straight and square, and is scarfed together with coaks, with tarred flannel between each scarf, which are firmly bolted together and caulked.

The rabbet for receiving the plank of the bottom may be trimmed out, leaving about a foot at each end of the scarfs, for the better caulking the butts. In the navy, the rabbet is lined parallel to the upper side of the keel to the thickness of the bottom plank; but, in most merchant-ships, the rabbet is taken out of the middle of the keel, to prevent its canting, should the ship take the ground. The keel is set fair and straight along the middle of the blocks; and, to keep it in that position, tree-nails are driven along its sides into the blocks.

*Dead or rising-wood* is of oak timber, and fayed upon the upper side of the keel. The pieces along the midships are of a parallel thickness, and in breadth to overhang the keel about two inches on each side. The dead-wood afore and abaft, for the security of the half-timbers, is as high as the cutting-down. This part of the dead-wood below the stepping-line is trimmed to the shape of the body, and above the stepping, perpendicular to the size of the keelson. The scarfs or butts of the dead-wood should give scarf to the butts of the keel, and to each other.

*Stem* is composed of two or more pieces of oak timber, of the best quality, as shifting it is very expensive. It is sawn to its siding and moulding, then trimmed and scarfed together as the keel, and the rabbet taken out likewise.

On the stem should be marked, from the mould, the heights of the harpins, decks, cheeks, &c. and a line square from the keel, and a middle line as a guide to set it by.

*Apron* is also oak sawn to its siding and moulding, and fayed to the aft-side of the stem, to succour it at the scarfs, which are bolted through the apron, observing to place the bolts within the rabbets.

*Bollard-timbers* are oak sawn to their siding and moulding,

their heads in wake of the bowsprit to be left the thickness of the plank inside and out; they are fayed and coaked to the sides of the stem and apron, and bolted through, where practicable, observing to place the bolts clear of the deck-hooks. Sometimes oak fillings are fayed between the stem and bollard-timbers, to keep them more open in wake of the bowsprit.

*Hawse-pieces* are oak sawn to their siding and moulding, and are fayed to the bollard-timbers, and to each other, in wake of the hawse-holes; and are opened above and below the hawse-holes, for the admission of air, to about one inch and a half. When in their places, they are to be bolted to the bollard-timbers and each other, clear of the hawse-holes and breast-hooks. Let it be observed, that the hawse-pieces should be so disposed as to be equally cut by the hawse-holes.

*Stern-post* is oak sawn to the siding and moulding, and should be provided for the top, and to work upwards, if to be got. The rabbet is trimmed out on each side, to receive the plank of the bottom, to the shape of the body; and a tenon left on the heel, one-third the depth of the keel.

*Inner-post* is oak sawn to a parallel breadth, and sided, as the shape of the body may require, below the head: it is fayed to the fore-side of the stern-post, and a tenon is made on the heel as on the main-post, and the head left long enough to tenon an inch into the transom next above it.

*Transoms* are oak sawn to their siding, whether rounding upwards or straight; and to the moulding by their respective moulds. The wing-transom, if sawed only to the margin bevelling, may be brought in for other uses, if found defective; for transoms require much trouble and expence to shift them; the quality of the timber ought, therefore, to be of the best, and quite free from any defect whatever. In converting the transoms, let care be taken to work them top and butt alternately.

The transoms are to be trimmed with the greatest nicety, and then let on the post, with scores on each side of about an inch; observing the greatest exactness in letting them down, and that they stand at right angles with the middle line on the post. The ends, when cut off to the mould, are left one inch and a half longer, to tenon and face on to the aft-sides of the fashion-piece. The ends may be opened or mouthed, to admit the air.

*Fashion-pieces* are oak sawn to their siding, then to the mouldings and bevellings; and, when trimmed, let on to the ends of the transoms, in the manner already described.

*Frame-timbers* are oak sawn to their siding, straight, and out of winding, then moulded and sawn to their respective bevellings, except the cant-floors, which are sided to their proper cant.

The frame-timbers should be converted of sound well-grown timber, without sap or vein appearing in wake of the ports, and sawn full to their sidings, so that their scantling may remain after the ports are trimmed out. Every timber should also be provided to its length, consequently each should stand upon its proper head; or if one timber happens to be short, provide the next long enough to make good the deficient length, as *through-chocks* should always be rejected, or only admitted on extraordinary occasions. The heads and heels of all the timbers to have one-third of the substance left the moulding way, when trimmed; and the seats of the chocks should not exceed once and a half the siding of the timber.

In providing the floors, care should be taken to reverse the butt end of each succeeding floor, because the tops may

## SHIP-BUILDING.

sometimes be scanty; and, when short of the floor-head, may be admitted, if the second futtock runs down and meets upon its respective floor.

All floors are required to have sufficient wood to seat themselves on the dead-wood, and the throats to run up to the cutting-down or under side of the keelson; then any wood wanting below the seating may be made good by a chock.

The floors, when correctly trimmed, are let down into scores cut in the dead-wood, to the exact height of the cutting-down from the upper edge of the rabbet of the keel, in their respective situations; set precisely level, and at right angles with the middle line of the keel. The floors are then ribbanded and shored, securing the floors at the head and heel to prevent any alteration; for the truth and precision of the whole fabric may be said to depend upon the accuracy of the floors, when got into the ribband.

*Futtocks.*—The several futtocks are trimmed straight, and out of winding on the joint side; and the lower futtocks in the navy run down to the side of the dead-wood, but in merchant-ships they are from nine to twelve inches short of the keel, that water may not lie above the ceiling. The wood wanting on the inside of the lower futtocks, in the navy, is made good by cross-chocks up to the cutting-down.

The timbers that compose a frame, or bend, are bolted together, either close or opened, as required; the joint-side of the second futtock to the joint-side of the lower futtock, to the middle of its length or scarfing, and bolts thereto with three bolts of square iron. The heel of the third futtock joins the head of the lower futtock, and bolts, as the former, to the second futtock; the heel of the fourth futtock joins to the head of the second futtock, and bolts to the third; and the heel of the top-timber scarfs on the head of the third futtock, and is bolted or fastened with tree-nails to the fourth futtock, taking care that no bolts are driven in wake of the ports or port-fills.

They are raised into their places by sheers and tackles, and great care should be taken that the frame be not strained in hoisting, as its form would be altered, and of consequence the true shape of the body lost; to prevent which, the joints of the chocks and heads are secured by nailing quarter over them, and a shore fitted on the inside or bag of the frame.

The frames, as hoisted, are kept to their true breadth, and equally distant from the middle line, by the cross pales, which are nailed at the main height of breadth, or in the ports: the latter is preferable, if not thought too high, because the ends need not be cut, and they may remain till the ship is planked, and the beams in and kneed.

The frames are next ribbanded thus: the cant-frames may be gotten near to their stations by the harpin-moulds, then the harpins gotten up; and, if the frames come fair, may be nailed and shored to their firmarks.

The square frames, corresponding at the floor-firmark or guide, must be levelled, and the joints set at right angles with the middle line, observing that the spacing of the ports agrees. The ribbands may then be nailed and shored, and the lower futtocks bolted to the floors.

*Filling-timbers*, or the timbers between the frames, are trimmed and hoisted into their places separately; then equally spaced asunder, and nailed to the ribbands; then choaked at their heads and heels, and the whole frame dubbed fair inside and out to its scantling for planking.

*Keelson* is oak sawn to its siding and depth, or moulding, then fayed along the middle of the floors, and bolted through every floor and the keel, with three or more douls

on each scarf, which should give as much shift as possible to the scarfs of the keel. For some years a three-inch oak plank has been fayed upon the upper side of the keelson, and the bolts driven through that likewise.

*Stemson* is oak sawn to its siding and moulding, then trimmed and fayed to the *apron*, and scarfed with a hook or douls into the fore part of the *keelson*. The bolts through the *breast-hooks* must be considered, and one or two bolts may then be driven through between them.

*Sternson-knee* is oak sawn to its siding and moulding, then trimmed and fayed against the transoms and upper side of the *dead-wood*, and scarfs with a hook, or douls into the after-piece of the *keelson*. It is bolted to the transoms and stern-post as the keelson, of which it is a continuation.

*Wales* are next wrought, and the *thick-stuff* below them: they should be fastened with dumps only for the present, as the tree-nail holes, which are double and single alternately in every timber, and should be left open as long as possible, for the admission of air. A doull in the timber next each butt in the wales, in the strake above and below it, has been lately introduced in the navy, as an additional security. The wales and diminishing strakes are then dubbed down fair, and large cleats nailed at the fore part of every port, to which the ship is substantially shored.

*Planking.*—The bottom is next planked down sufficiently low to work the orlop-clamps. See *Planking expanded*, Plate VIII.

*Inboard Clamps, Thick-stuff, &c.*—These are wrought similar to the outside stuff above. The clamps to the sheer of the deck, and their upper sides to the round-up of the beam, and the lower edge, square to the timbers, unless they work down to the ports; then, in wake of the ports, the lower sides are trimmed level, and between the ports square to the timbers. Clamps over ports are bearded from half their depth to one inch less in thickness on the under side, excepting over the ports, where the wood is left on, for the muzzles of the guns to house to; and the butts are douelled as the wales.

The thick-stuff is to be wrought with a square close edge over the joints of the timbers; and the spirittings are to have a seam allowed, agreeable to the thickness with the outside stuff, which should be a full sixteenth to every inch in the thickness.

*Beams* are sawn to their siding, and to the moulded depth square to the siding. Beams of two, three, or four pieces are scarfed together; and if in three or four pieces, the middle pieces may be fir, excepting in the hatchways.

Beams in two pieces have a scarf one-third the whole length of the beam. Beams in three pieces have the middle pieces and the end pieces each half the length of the whole beam, the middle piece having a scarf each way to take the arms. Beams made of four pieces have two middle pieces, each similar to the former: the arms and middle pieces are each to be in length three-sevenths of the whole length of the beam. See *Gun-deck*, Plate VI.

Beams are either tabled or douelled, and bolted together at the scarfs: if tabled, the lengths of the tables are once and a half the moulded depth in length, and divided at the middle of the depth; and where the wood is taken out on the upper side, it is left on the lower side, and so alternately; taking the wood out on the upper side at the table next the butt, as it will the better hang and support the lip. At each lip, beyond the tables, is a coak about six inches long; and next to that is a straight lap, about the same length.

The beams, when cut off to their length, have their ends mouthed and charred, and then are let down about one inch

into the clamps, at their several stations, at right angles with the middle line; keeping their upper sides out of winding with the beam line.

*Knees.*—The beams, at their ends, are connected to the sides by knees, or other substitutes for knees. The knees are sawn or trimmed to their siding, and fayed to the side, taking as little wood as possible out of the throat of the moulding way, as the greatest strength of the knee is there. Each knee tapers towards the toe to which it is sided; and the substance in the throat should be about twice and a half the siding, and not to admit of any chock that would reduce the knee at any part less than the siding.

Each knee should have two douls in the beam-arm, and from three to four bolts; and the two upper bolts in the side-arm of the hanging-knees should be kept up as high as possible, and the others equally spaced to the toe, and bored as square to the side as the seams outside will allow.

In those parts of the ship afore and abaft, where wooden knees cannot be procured of kindly growth, (for upon that depends the strength,) knees of iron are generally placed. These, although much used, particularly in merchant-ships, cannot be so fully depended upon as those of wood, because they cover less surface, are no wise flexible, nor can the bolts be driven so tight in iron as in wood. If, therefore, the ship strains, they must inevitably work loose. Again, the holes must be bored in the direction in which the knees are punched, so that where iron knees are intended to be placed, oak fillings should be driven between the timbers; otherwise the bolts may come in the openings, which is inadmissible. Besides this, the bolts may come in the seams of the outside plank; when it so happens, the best way is to cut out a piece, and clench the bolt upon the timbers.

Bolts in wooden knees are mostly driven from the outside, and clenched upon the knees inside; but bolts in iron knees are driven from the inside, with collar or stout heads, because upon the head depends its fastening; or if the bolts be of copper, they must have a ring under the head, and the head spread or made large in driving. All bolts driven from the inside should be carefully clenched upon a ring, let flush into the plank, by means of a machine or centre-bitt for that purpose, and the points under water carefully caulked after the ring is let in.

Wooden knees having become scarce for some years past, many substitutes have been attempted; and iron knees, or rather knees formed of iron and wood conjointly, are certainly best when properly applied. See SUBSTITUTE.

*Standards*, either on the deck or to the sides of orlop beams, are so similar to knees, as to require no further description.

*Breast-hooks, steps, and crutches*, are oak sawn to their sidings, then moulded. The deck-hooks are fayed to the timbers, the others to the inside stuff. The holes for the bolts are bored alternately, near the edges, equally asunder, and square with the body. Breast-hooks, steps, and crutches, are assisted in the moulding by chocks; and the deck-hooks may be assisted by large cakings, worked behind them. All the chocks, &c. are douelled or tabled, and ought on no account to have less wood or substance than their siding, clear of the chock.

*Riders* are oak sawn to their siding, moulding, and bevellings; then fayed to their respective places, as follows.

*Floor-riders* in two pieces have a cross-chock fayed over the heels, with a hook and butt scarf; their heels run down to the limber-strake, and the heads run upwards between the joints of the floor-heads and first futtock-heads.

*First futtock-riders* lay close to the sides of the floor-riders, and their heels extend downwards within four feet

of the keelson: their heads run upwards between the joint of the first futtock-head and under side of the orlop-beams; with a cross-chock fayed over the heels as the floor-rider.

*Second futtock-riders* lay close to the sides of the first futtock-riders, and scarf with a hook-scarf under the head of the floor-riders, or connect thereto with a chock. Their heads run up within two inches of the under side of the gun-deck beam, and are sawn with a swell at the orlop-beam, to which they tail sideways; and they bolt through the beam and the adjoining riders fore and aft.

*Third futtock-riders* lay and bolt to the sides of the second futtock-riders, and are sawn with a swell, as the above, at the gun-deck beam. The heads run up within two inches of the under side of the upper deck beam, or middle deck, in three-deck ships; and the heels come within two inches of the upper side of the orlop-beam.

Ships in the navy at present have no inside stuff below the clamps, but have their timbers filled in between with dry slices of oak, driven in tight and caulked; and the riders are fayed over the timbers, and stand diagonally at the angle of forty-five degrees.

The *knee of the head* is oak, each piece sawn to its siding, agreeable to the tapered battens, where they intersect. The main piece should make the lower part of the knee, and run up to the fore part of the stem, to which it lays high enough for a hole to be cut in it to receive the main-stay collar. The front piece runs up to seat the figure, and should be broad enough to take the bobitay holes, and the lower end step in the main piece about one foot below the load draught of water. Another piece must be provided to make the lacing to secure the figure. The other pieces between may then be provided, as most convenient, marking on the mould the shape of each piece, as provided; the surface of each piece is then fayed close together, and douelled. The knee is hoisted up into its place, and then bolted with seven or more bolts through the stem and apron, and sometimes through the deck-hooks.

*Cat-heads* are now sawn straight, sideways, and plumb, moulded to slight, in ships of the line, to five inches in a foot above a level line without the bow; and in frigates and smaller vessels, to the angle of forty-five degrees. The inner end lays up to the under side of two or more of the forecable beams, so as to stand square with the bow.

*Supporters* of the cat-heads are knees of oak fayed to the under side of the cat-head, and the arm to the side to stand perpendicular; the upper arm bolted through the cat-head, and the other through the side.

*Rudder.*—The main piece to be oak sawn to its siding, and the upper part to the given dimensions, and the lower part to be moulded as broad as the piece will admit. Whatever the main piece may require to complete its fore-side may be elm, fayed close to the main piece, and douelled. The other pieces to complete the surface of the rudder may be fir, fayed close to the main piece and each other, and douelled. The whole is then trimmed straight through to its thickness, and bolted together between the straps of the pintles. The back is then fayed on, and fastened to the aft-side, and the sole at the heel, when cut off to its length, which is nine inches short of the under side of the keel. The fore-side may be then bearded from the middle to two-fifths the thickness, lined down on each edge; but this has been found to cut or wound the main piece so much at the upper pindle, that, lately, the aft-side of the stern-post is likewise bearded at the upper end; and consequently the fore-side of the rudder so much the less. The pintles may next be let on thus: the braces being let on to the stern-post, and square from the aft-side, a staff of the whole length

length is run down through the holes of the braces. Now mark the upper sides of the braces correctly on the staff with a pencil, or both under and upper sides will be best. Then mark on the staff the upper side of the wing-transom, and the under side of the deck-transom above; also the upper side of the deck; and, lastly, the under side of the keel. Next apply the staff on the fore-side of the rudder, and exactly mark off the upper sides of the braces in the middle line, likewise the transoms and deck. Then square down, from the fore-side of the rudder, the upper side of each brace, which, it may be observed, is the under side of the pintles. Now set upwards the breadth of the straps of the pintles, and the scores may be taken out till their crowns come flush with the bearding, and the middle of the pintles ranges well with the middle line: thin copper is drest in the scores under the pintles. Scores or throatings are then gouged out, under the pintles, sufficiently large for hanging the rudder, which may be formed by a piece of sheet-lead made to the crown of each brace, and traversed round its respective pintle. Let there be sufficient room in the scores to allow for the sheathing; and that the rudder may hang easily, all the scores must be made to the length of the lower one; that pintle being two inches longer than the others. The score nearest the load water-line is opened on one side to fit in the wood-lock, which prevents the rudder from unshipping. Ships built in the North have the pintles put into the braces, and the rudder put together in that situation, so that it cannot be unhung until throatings are cut to clear it of the braces.

After the braces are let on to the stern-post, it is best to try all the pintles in them, and see that they work easily in the braces, and square from the stern-post. Then their upper sides may be marked on the stern-post, and set off on the rudder, as before directed, without the possibility of error.

The head, if not round-headed, is thirder and bearded back about three-quarters of an inch, and the edges taken off to a bold round. The holes for the tillers may now be cut through the lower hole three inches clear of each transom, and the lower part of the upper hole three inches clear of the deck: lastly, the head-hoops may be driven on.

Amongst other useful machines for drawing bolts out of ships (see BOLTS), the following was invented by Mr. William Hill. See Transactions of the Society for the Encouragement of Arts, &c. vol. x.

“First, The use of this machine is to draw the keelson and dead-wood bolts out, and to draw the knee of the head bolts. Secondly, The heads of the keelson bolts heretofore were all obliged to be driven through the keelson, floor-timbers, and keel, to get them out: by this means the keelson is often entirely ruined, and the large hole the head makes materially wounds the floors; and frequently, when the bolt is much corroded, it scars, and the bolt comes out of the side of the keel. Thirdly, The dead-wood bolts, that are driven with two drifts, are seldom or never got out, by which means the dead-wood is condemned, when some of it is really serviceable. Fourthly, In driving the knee of the head bolts, sometimes the knee starts off, and cannot be got to again, but is furred up; but with this machine it may be drawn to again.”

In Plate XIV. *Ship-building*, fig. 3, A, A represent two strong male screws, working in female screws, near the extremities of the cheeks, against plates of iron, E, E. CC is the bolt to be drawn, which, being held between the chaps of the machine at DD, is, by turning the screws by the lever B, forced out of its hold. F, F are two dogs, with hooks at their lower extremities, which, being driven into the plank, serve to support the machine till the chaps

have got fast hold of the bolt. At the upper part of the dogs are rings passing through holes in a collar, moveable near the heads of the screws.

Fig. 4. is a view of the upper sides of the cheeks, when joined together; *a, a*, the holes in which the screws work; *b*, the chaps by which the bolts are drawn. Fig. 5. the under side of the cheeks; *a, a*, the holes in which the screws work; *b*, the chaps by which the bolts are drawn, and where the teeth that gripe the bolt are more distinctly shewn. Fig. 6, one of the cheeks separated from the other, the letters referring, as in figs. 4 and 5.

SHIPFUND, SHIPPOND, or *Schiffsfund*, in Commerce, a large weight in Holland, Germany, Denmark, and Sweden, containing a different number of pounds in different places. At Amsterdam the shippond contains 3 centners, 20 lysponds, 37½ steen or stones, and 300 lbs. A lyspond is 15 lbs., and a stone 8 lbs. At Berlin a ship-laft contains 12 shipfunds, each of 20 lysponds, or 280 lbs.; in all 3360 lbs.: but a laft of salt is 3260 lbs. At Hamburg a shipfund contains 2½ centners, 20 lysponds, or 280 lbs.: a lyspond is 14 lbs., and a centner 112 lbs. Hamburg weight. At Copenhagen the shippond contains 3½ centners, 20 lysponds, or 320 lbs.; a lyspond is 16 lbs., and a centner 101 lbs.

SHIPLEY, JONATHAN, in *Biography*, an English prelate, was born in the year 1714, and was educated at Christ-church, Oxford, where he wrote some verses on the death of queen Caroline; and in 1738 he took his degree of M.A. Soon after this he entered into holy orders, and obtained a living. In the year 1743 he was installed prebendary of Winchester, and in 1748 appointed chaplain to the duke of Cumberland, whom he accompanied abroad. In 1749 he became canon of Christ-church, and in 1760 dean of Winchester. In 1769 he was advanced to the bishopric of St. Asaph. He died in 1788. He was author of poems, and sermons on public occasions.

SHIP-MONEY, an imposition which was anciently charged upon the ports, towns, cities, boroughs, and counties of the realm; by writs commonly called *Ship writs*, under the great seal of England, for the providing and furnishing certain ships for the king's service.

This imposition was revived by king Charles I. in the years 1635 and 1636; but by stat. 17 Car. I. it was declared to be contrary to the laws and statutes of the realm, claim of right, liberty of the subject, &c.

SHIPPANDSTOWN, in *Geography*, a town of Virginia, on the south side of the Patowmack; 40 or 50 miles from Alexandria.

SHIPPENSBURGH, a post-town of Pennsylvania, in Cumberland county, on a branch of Conadogwinnet creek, which discharges itself into the Susquehanna; containing about 200 houses, chiefly built of stone, 1159 inhabitants, and three meeting-houses, one for Seceders, one German, and one Methodist. It derives its name from its proprietor John Shippen, esq. of Philadelphia, who leased out the place in small house-lots on ground-rents from two to four dollars a year; 146 miles W. of Philadelphia.

SHIPPER, SKIPPER, or *Schipper*, a Dutch term, signifying the master of a ship.

We also use the word, popularly, for any common seaman.

SHIPPICAN ISLAND, in *Geography*, an island in the gulf of St. Lawrence, on the south side of Chaleur bay, S.W. of, and separated by a narrow channel from, Miscow island.

SHIPPING denotes a multitude of vessels.

SHIP-SHAPE, in *Sea Language*, denotes the fashion of a ship, or the manner of an expert sailor: thus, they lay,

say, the mast is not rigged *ship-shape*, and trim your sails *ship-shape*.

SHIPSTON-UPON-STOUR, in *Geography*, a market-town in the upper division of the hundred of Oswaldslow, and county of Worcester, England, is situated in a district entirely detached from the body of the county, and close to the left bank of the river Stour, whence is derived the latter part of its name. The houses here are chiefly built of stone; but notwithstanding this advantage, the town cannot boast much of its appearance, many of them being small, and thatched with straw. Several attempts have been made to establish manufactures here, but without any permanent success. The market-day is Friday, weekly; and there are two annual fairs, one on the 22d of June, and the other on the first Tuesday after the 10th of October; both of them for horses, cows, and sheep. The manor of Shipston formerly belonged to the priory of Worcester, and is now part of the possessions of the dean and chapter. The church is only a chapel of ease to the mother church of the parish of Tredington, which extends about nine miles in length and two in breadth. According to the population returns of 1811, the parish contains 297 houses, and 1377 inhabitants, of whom about 1000 reside within the township of Shipston-upon-Stour. Nash's Survey of Worcestershire, 2 vols. fol. Beauties of England and Wales, vol. xv. by Mr. Laird, 8vo. 1813.

SHIPTON, a flourishing township, of excellent land, in Lower Canada, on the east bank of the St. Francis; 20 miles N.W. of Ascot, and containing about 356 inhabitants.

SHIPWRECK. See WRECK.

SHIRAVARD, in *Geography*, a town of Persia, in the province of Ghilan; 30 miles S. of Aitara.

SHIRBEY, a town of Syria, the residence of a scheik; 15 miles E. of Aleppo.

SHIRBORN, a river of England, in the county of Warwick, which runs into the Sow.

SHIRE, SCYRA, originally Saxon, *scir*, or *scire*, formed from *scyran*, to divide; a part or portion of the land, called also a county; which see.

SHIRE-Clerk, he that keeps the county court; and his office is so incident to that of the sheriff, that the king cannot grant it away.

SHIRE-Man, was anciently the judge of the shire, by whom trials for land, &c. were determined.

SHIRE-Mote, in our *Old Writers*, an assembly of the county or shire at the assizes, &c. See SCYREGEMOT.

SHIRE-Reve. See SHERIFF.

SHIRE, Knights of the. See KNIGHT.

SHIREWOOD or SHERWOOD *Forest*, in *Geography*, is an ancient and extensive forest, comprehending a large portion of the county of Nottingham, England. Thoroton, in his History of Nottinghamshire, says that it stretches into the hundreds of Broxton, Thurgarton, and Bassetlaw; and measures about twenty-five miles in length, by from seven to nine in breadth, an extent which seems to agree with its ancient boundaries, as stated in a perambulation made in the sixteenth year of Henry III. The period when this district was originally constituted a forest is unknown, but that event must have occurred previous to the time of Henry II., as in the first year of that monarch's reign, it appears from official records, that William Peverel was called upon to answer "De Placitis Forestæ in Comitatu Nottingham." At that time Peverel had the whole profit and command of this forest; but it must soon afterwards have reverted to the crown, for in 1161 the sheriff of the county prays to be discharged of "4*l.* in vasto forestæ;" and in 1163 he prays for a similar discharge, and for the discharge of "40*l.* paid to

the canons of Shirewood for alms." In the Forest books is inserted a copy of a charter by king John, granting to Matilda de Caux, and Ralph Fitzstephen her husband, and their heirs, all the liberties and free customs which any of the ancestors of the said Matilda, lords of Laxton, had held in Nottinghamshire, including the forest of Shirewood. The same rights afterwards fell to John Birking, as heir-general to Matilda de Caux; and in 1226 the forest is mentioned as being then in possession of his son; but this line failing, it descended to the family of the Everinghams, who having lost their possessions by forfeiture in the reign of Edward I. it reverted to the crown. Since that event, its civil jurisdiction has been generally vested in the sheriffs of the county, and its forest jurisdiction only granted to various individuals among the nobility and gentry, as special marks of royal favour. An inquisition taken before Geoffrey de Langley, in the reign last mentioned, illustrates the customs of this forest. By it the chief keeper appears to have been obliged to have three deputy keepers for a like number of districts, in order to attach all trespasses, and present them at the attachment before the verdurers. In the first keeping, which lay between the rivers Lene and Doverbeck, he was to have one forester riding with a page, and two foresters on foot; two verdurers, and two agisters. This keeping contained the three hays of Bakwood, Lindeby and Willay. The High Forest, including the hays of Birkland and Bilhagh, and the park of Clipstone, formed the second keeping; and here were two foresters riding, with two pages and two agisters. The third keeping, Rumwode, had one forester on foot; two woodwards, one at Carburton, and the other at Buddy; and the same number of verdurers and agisters. The chief keeper was further bound to have a page bearing his bow, whose duty it was to gather "chiminage," which is usually supposed to have been a tax for the formation and preservation of roads.

By the last survey made of this forest in 1609, it was parcelled out into three walks, called the north, middle, and south walks. The forest officers, under the superintendance of the chief justice in eyre north of Trent, are a lord warden, a bow-bearer and ranger, four verdurers, a steward, and nine keepers, besides two sworn woodwards for Sutton and Carleton. The surveyor-general of the woods has likewise a jurisdiction over this forest, as far as regards the wood and timber of the crown. He has a deputy in the forest, who has a fee-tree yearly, and a salary of 20*l.* Thorney-wood Chase, though a branch of this forest, is distinct from it in jurisdiction, having been granted by queen Elizabeth to John Stanhope, esq. and his heirs, as hereditary keepers. This chase comprehends a large portion of the south walk, and was formerly well stocked with fallow deer; but these, of late years, have greatly diminished in number.

Of the ancient woodland in this extensive tract, little remains except in the hays of Birkland and Bilhagh, which form an open wood of large old oaks, covering about 1500 acres of ground; but modern plantations have lately increased rapidly, and there are, in different districts and parks, a few trees, remarkable alike for their great age and magnitude. In Clipstone park is an immense oak, called the Parliament oak, from a tradition that a parliament was assembled here by Edward I.; and in the same park is another tree, styled the Broad oak, the bole of which measures 27½ feet in circumference. Many of these venerable oaks may likewise be seen in Welbeck park, on the skirts of the forest, where some of them are upwards of 34 feet round. Rooke, in his "Sketch of the Forest," mentions a recent discovery of a very curious mode of ascertaining the great antiquity of some of these trees. He tells us, that in cutting down some timber in Birkland

Birkland and Bilhagh, letters were found cut or stamped in the body of the trees, denoting the king's reign in which they were so marked. The cyphers were of king John, James I., and William and Mary. The mark of John was eighteen inches within the tree, and about a foot from the centre; it was cut down in 1791; but the middle of John's reign was 1207, from which, if we subtract 120, the number of years requisite for a tree of two feet diameter to arrive at that growth, it will make the date of its planting 1087.

The forest of Shirewood was, in ancient times, frequently the scene of royal amusement. As early as the reign of Henry II., Mansfield was the general residence of the court upon these occasions, and it was in this vicinity, according to tradition, that Henry made acquaintance with the miller of famous memory, sir John Cockle. This forest was likewise the retreat of another personage, equally celebrated in the chronicle of ballad, the illustrious Robin Hood, who, with little John, and the rest of his associates, making the woody scenes of it their asylum, laid the whole county under contribution. Thoroton's History of Nottinghamshire, republished, with additions, by John Throsby, 3 vols. 4to. 1790. Beauties of England and Wales, vol. xii. by Mr. Laird, 8vo. 1813.

**SHIRINKI**, one of the Kurile islands, about 26 versts from Poromushir. On it rises a round mountain-top; and about it, on the coast, walls of rock and loose brittle stone, but it has no sandy bay, nor any safe inlet for shipping. The island is nearly as broad as it is long, and may be about 40 versts in circumference. It is only inhabited by sea-lions and other marine animals, with some red foxes and sea-fowls that have been carried thither with the ice. There is no wood on the island, except a few sticks of the mountain pine and some elder bushes; and it has neither a stream nor a spring of water. The rocks are very much disposed to break and fall in fragments. N. lat.  $50^{\circ} 40'$ . E. long.  $138^{\circ} 3'$ .

**SHIRLEY, ANTHONY**, in *Biography*, the second son of Thomas Shirley of Welton, in Suffex, a celebrated traveller, was born in 1565. He studied at Oxford, where he took his bachelor's degree in 1581, after which he joined the English troops, which, at that time, were serving in Holland. In 1596 he was one of the adventurers who went to annoy the Spaniards in their settlements in the West Indies, and on his return he was knighted. After this he was sent by the queen into Italy, in order to assist the people of Ferrara in their contest with the pope: before, however, he arrived, all the disputes were accommodated, and peace was signed; he accordingly proceeded to Venice, and travelled from thence to Persia, where he came in great favour with Shah Abbas, by whom he was sent ambassador to England in 1612. By the emperor of Germany he was raised to the dignity of count, and by the king of Spain he was appointed admiral of the Levant seas. He died in Spain about the year 1630. There is an account of his West Indian expedition in the third volume of Hacluyt's Collection, under the following title: "A true Relation of the Voyage undertaken by Sir Anthony Shirley, Knight, in 1596, intended for the Island San Tome, but performed to St. Jago, Dominica, Margarita, along the Coast of Tierra Firma to the Isle of Jamaica, the Bay of Honduras, Thirty Leagues up Rio Dolce, and homewards by Newfoundland, with the memorable Exploits achieved in all this Voyage." His travels into Persia are printed separately, and were published in London in 1613; and his travels over the Caspian sea, and through Russia, were inserted in Purchas's Pilgrimages.

**SHIRLEY, JAMES**, a poet and dramatic writer, was born in London about the year 1594. He received the early part of his education at Merchant Taylors' school, from which place he was removed to Oxford. He was, on ac-

count of his talents, patronized by Dr. Laud, who, however, would not consent to his taking orders, by reason of his being disfigured by a large mole on his cheek, which, in his estimation, according to the canons of the church, rendered him unfit to officiate in clerical duties. Shirley therefore left Oxford without a degree; but he afterwards removed to Cambridge, and meeting with no farther obstacle, he took orders, and obtained a curacy. His religious creed was not sufficiently settled, and he went over to the church of Rome, abandoned his cure, and opened a grammar-school at St. Alban's. After some time he deserted this employment, and became a writer for the stage. His productions were successful, and he acquired a reputation which caused him to be taken into the service of queen Henrietta-Maria. When the civil war broke out, he accompanied the earl of Newcastle in his campaigns, and also assisted him in the composition of several of his plays. On the ruin of the king's cause he came to London, and resumed his occupation of a school-master, in which he met with considerable encouragement, and he shewed his attention to the duties of his office, by publishing some works on grammar.

During the Commonwealth, theatrical amusements being suspended, Shirley had no room in which he could display his dramatic talents; but after the Restoration, several of his pieces appeared again on the stage. The death of this author is thus described: his house in Fleet-street being burnt in the great fire of London, in the year 1666, he was forced with his wife to retreat to the suburbs; in consequence of the loss and the alarm which this occasioned, both himself and wife died within a few hours of each other, and they were buried in the same grave.

Mr. Shirley was author of thirty-seven plays, consisting of tragedies and comedies, and of a volume of poems, published in 1646. He had the reputation of being the chief among the second-rate poets of his time, but his works have long since disappeared from the stage, and they are scarcely ever referred to by more modern authors, yet there have been critics who thought highly of them. Dr. Farmer, in his Essay on the Learning of Shakspeare, says the imagination of Shirley is sometimes fine to an extraordinary degree. He assisted Mr. Ogilvie in his translation of Homer and Virgil, by writing notes on them.

**SHIRLEY**, in *Geography*, a township of America, in Massachusetts, in the N.W. part of Middlesex county; 41 miles N.W. of Bolton: incorporated in 1753, and containing 814 inhabitants.—Also, a township of Pennsylvania, in Huntingdon county, containing 862 inhabitants.

**SHIRON**, or **SCHIRVON**, a town of Thibet; 120 miles N. of Catmandu. N. lat.  $30^{\circ} 10'$ . E. long.  $85^{\circ} 5'$ .

**SHIRVAN**. See **SCHIRVAN**.

**SHISNIEZ**, a town of Poland, in Volhynia; 12 miles N. of Constantina.

**SHITAKOONTHA**, a name of the Hindoo deity Siva. It means the *blue-throated*; and the fable accounting for the name is often alluded to in the writings of that fanciful people. It relates, that when the ocean was churned, in the manner described under our article **KURMAVATARA**, poison was produced among the fourteen precious articles resulting from that marvellous operation. The word, as well as poison, means medicinal drugs. This was swallowed by Siva.

"To soften human ills, dread Siva drank  
The poisonous flood that stained his azure neck."

In the songs of Jayadeva, translated by sir W. Jones, in praise of Vishnu and Lakshmi, under their names of Krishna and Radha, the following passage occurs, which we are introduced

duced to extract as an instance of the playful gaiety of Hindoo poetries, and the prevalence of mythological allusions, in all their writings. Heri and Narayana, we may premise, are names of Vishnu; and Padma, or the Lotus, of Lakshmi.

“ Whatever is delightful in the modes of music; whatever is divine in meditations on Vishnu; whatever is exquisite in the sweet art of love; whatever is graceful in the fine strains of poetry;—all that let the happy and wise learn from the songs of Jayadeva, whose soul is united to the foot of Narayana. May that Heri be your support, who expanded himself into an infinity of bright forms, when, eager to gaze with myriads of eyes on the daughter of the ocean, he displayed his great character of the all-pervading deity, by the multiplied reflections of his divine person in the numberless gems on the many heads of the king of serpents, whom he chose for his couch: that Heri, who, removing the lucid veil from the bosom of Padma, and fixing his eyes on the delicious buds that grew on it, diverted her attention by declaring, that when she had chosen him as her bridegroom, near the sea of milk, the disappointed husband of Parvati drank in despair the venom which dyed his neck azure.” Jones’s Works, vol. x. Af. Ref. vol. iii.

The many-headed king of serpents is named Seshha, a frequent subject of poetical exuberance. See SESHHA.

Of the blue-necked Siva, Nilakantha is another name, of similar meaning as that at the head of this article; and which indeed occurs oftener than Shitakantha, or Shitakoontha.

SHITTAT, in *Geography*, a town of Arabia Deserta; 50 miles W.N.W. of Melched Ali.

SHITTEN BAY, a bay on the W. coast of the island of St. Christopher.

SHIVAL, a town of Hindoostan, in Visiapour; 25 miles E. of Baddammy.

SHIVERAPILLY, a town of Hindoostan, in the circle of Cicacole; 20 miles W. of Cicacole.

SHIVERS, in a *Ship*, the seamen’s term for those little round wheels in which the rope of a pulley or block runs. They turn with the rope, and have pieces of brass in their centres, which they call the *coak*, with holes in them, into which the pin of the block goes, and on which they turn.

These shivers are usually of wood, but some are of brass, as those in the beels of the top-malts. See SHEAVE.

SHIVERS, in *Rope-making*, the foul particles taken from the hemp, when hatching.

SHIVERING, the state of a sail when the wind is too oblique to fill it, so that it flutters about. This must be the case when a vessel is put about, till the sails are filled again with the wind.

SHIVERY SALT, a name given by the salt-workers to a sort of salt, very little different from the common brine-salt. See SALT.

SHIUMLA, in *Geography*, a town of Bulgaria, in the sangiac of Driitra. In this place, thought by the Turks to be impregnable, they were defeated by the Russians with terrible slaughter; 62 miles E. of Varna. N. lat. 43° 10′. E. long. 26° 27′.

SHIZAR, a town of Syria, in the pachalic of Aleppo; 15 miles S.E. of Famieh.

SHOAD, in *Mining*, a term for a train of metalline stones mixed with earth, sometimes lying near the surface, sometimes at considerable depths, but always serving to the miners as a proof that the load or vein of the metal is thereabout. The deeper the shoad lies, the nearer is the vein.

SHOAD-Stones, a term used by the miners of Cornwall,

and other parts of this kingdom, to express such loose masses of stone, as are usually found about the entrances into mines, sometimes running in a straight course, from the load or vein of ore to the surface of the earth.

These are stones of the common kinds, appearing to have been pieces broken from the strata, or larger masses, but they usually contain mundic or marcasitic matter, and more or less of the ore to be found in the mine. They appear to have been at some time rolled about in water, their corners being broken off, and their surface smoothed and rounded.

The antimony mines in Cornwall are always easily discovered by the shoad-stones, these usually lying up to the surface, or very nearly so; and the matter of the stone being a white spar, or debased crystal, in which the native colour of the ore, which is a shining blueish-black, easily discovers itself in streaks and threads.

Shoad-stones are of so many kinds, and of such various appearances, that it is not easy to describe or know them: but the miners, to whom they are of greatest use in the tracing, or searching after new mines, distinguish them from other stones by their weight; for if very ponderous, though they look ever so much like common stones, there is great reason to suspect that they contain some metal. Another mark of them is their being spongy and porous; this is a sign of especial use in the tin countries, for the tin shoad-stones are often so porous and spongy, that they resemble large bodies thoroughly calcined. There are many other appearances of tin shoads, the very hardest and firmest stones often containing this metal.

When the miners, in tracing a shoad up hill, meet with such odd stones and earths, that they know not well what to make of them, they have recourse to vanning, that is, they calcine and powder the stone, clay, or whatever else is supposed to contain the metal; and then washing it in an instrument, prepared for that purpose, and called a *vanning shovel*, they find the earthy matter washed away, and of the remainder, the stony, or gravelly matter lies behind, and the metalline matter at the point of the shovel. If the person who performs this operation has any judgment, he easily discovers not only what the metal is that is contained in the shoad, but also will make a very probable guess at what quantity the mine is likely to yield of it in proportion to the ore. Phil. Trans. N<sup>o</sup> 69. Price’s Mineralogia, p. 124, &c.

SHOAL, in *Sea-Language*, is the same as *shallow*, and is applied to flats in the water.

They say it is *good shoaling*, when a ship sailing towards shore, they find by her sounding it grows shallower and shallower by degrees, and not too suddenly; for then the ship goes in safety.

SHOAL Inlet, in *Geography*, a channel between two small islands on the coast of North Carolina. N. lat. 34° 5′. W. long. 77° 58′.

SHOALNESS, a low cape on the west coast of North America. Captain Cook met with some Indians on the coast, near this cape, who came off to the ships in canoes, expressing, as he conceived, their pacific intentions by hallooing and opening their arms, as they cautiously advanced. At length some of them approached near enough to receive some trifles that were thrown to them. This brought on, says captain Cook, “a traffic between them and our people, who got dresses of skins, bows, arrows, darts, wooden vessels, &c.; our visitors taking in exchange whatever was offered them. They seemed to be the same kind of people that we had lately met with along this coast; wore the same ornaments in their lips and noses, but were far more dirty, and not so well clothed. They appeared to be wholly unacquainted with people like us;”

us; knew not even the use of tobacco; nor was any foreign article seen in their possession, unless a knife may be considered as such. This indeed was no more than a piece of common iron fitted into a wooden handle. They however knew the value and use of this instrument so well, that it seemed to be the only article they wished for. Most of them had their hair shaved or cut short off, leaving only a few locks behind, or on one side. As a covering for the head they wore a hood of skins, and a bonnet apparently of wood. One part of their dress was a kind of girdle, very neatly made of skin, with trappings depending from it, and passing between the legs, so as to conceal the adjoining parts. By the use of such a girdle, it should seem that they sometimes go naked, even in this high latitude, for they hardly wear it under their own clothing. The canoes were made of skins, like all the others we had lately seen; except that these were broader, and the hole in which the man sits was wider than in any I had before met with." N. lat. 60°. E. long. 198° 12'.

**SHOALS**, *Iles of*, or, as they were formerly called, **SMITH'S ISLANDS**, a group of small islands, situated on the coast of New Hampshire, in America. The line that divides the district of Maine from New Hampshire passes between these islands, leaving part in one of these states and part in another. They contain about 140 poor fishermen, who are supplied with a religious teacher by the society for propagating the gospel. They have a meeting-house, which serves as a landmark for seamen, and a parsonage-house, erected by charity. These islands consist chiefly of a barren rock, with little soil. N. lat. 42° 59'. W. long. 70° 33'.

**SHOAL-WATER BAY**, a bay on the N.E. coast of New Holland, W. of Cape Townhend.—Also, a bay on the W. coast of North America. N. lat. 46° 50'. W. long. 124° 10'.

**SHOAR**, or **SHORE**, a prop, or counterfort, set up to support any thing of weight which leans on one side.—See **BUTTRESS**.

**SHOARS**, or *Shores*, in *Ship-building*, are fir-baulks, spars, or pieces of timber, fixed under the ribbands, or against the sides and bottom of the ship, to prop or support her whilst building or repairing.

**SHOBA**, in *Geography*, a town of some note in Africa, in the kingdom of Dar-fur; 42 miles or 2½ days' journey W.S.W. of Cobbé. This place is said to be well supplied with water, and has near it some chalk-pits, which, when Mr. Browne visited them, were almost exhausted for the purpose of adorning the royal residence, and some others, with a kind of white-wash. In Shoba reside some Jolabs; the rest of the people are Ferians, and occupied in other pursuits.

**SHOCK**, or **SCHOCK**, in *Commerce*, a German word expressing 60 pieces.

**SHOE**, in *Geography*, a small island in the Pacific ocean, near the coast of Waygoo. S. lat. 0° 1'. E. long. 130° 53'.

**SHOE INDIANS**, Indians of North America, in an island of lake Missouri. N. lat. 48° 15'. E. long. 105° 45'.

**SHOE**, a covering for the foot, usually of leather.

Its structure, though the object of a particular art, is too popular to need explaining.

Its history is more obscure. Bend. Baudoin, a shoe-maker by profession, has a learned treatise of the ancient shoe, "De Solea Veterum," where the origin, matter, form, &c. thereof, are particularly inquired into.

Baudoin maintains, that God, in giving Adam skins of beasts to clothe him, did not leave him to go bare-footed, but gave him shoes of the same matter; that, after raw skins, men came to make their shoes of rushes, broom, paper, flax,

silk, wood, iron, silver, and gold; so different has their matter been. Nor was their form more stable, with regard either to the shape, colour, or ornaments; they have been square, high, low, long, and quite even, cut, carved, &c. Pliny, lib. vii. c. 56, tells us, that one Tychius, of Bœotia, was the first who used shoes.

M. Nilant, in his remarks on Baudoin, observes, that he quotes Xenophon wrongly, to shew that even in his time they still wore shoes of raw skins.

Xenophon relates, that the ten thousand Greeks, who had followed the young Cyrus, wanting shoes in their retreat, were forced to cover their feet with raw skins, which occasioned them great inconveniencies.

Nilant will not even allow, that the shoes of the country people, called *carbatine*, and *peronea*, were of crude skin, without any preparation.

The patricians, among the Romans, wore an ivory crescent on their shoes: Hellogabalus had his shoes covered over with a very white linen, in conformity to the priests of the sun, for whom he professed a very high veneration; this kind of shoe was called *σόδιον*, *udo*, or *odo*. Caligula wore shoes enriched with precious stones. The Indians, like the Egyptians, wore shoes made of the bark of the papyrus. The Turks always put off their shoes, and leave them at the doors of the mosques.

*SHOES made by rivetting instead of sewing.* A patent was taken out for this invention in 1809, by Mr. David Mead Randolph, an American. In his specification, he describes that the rivetting which he proposes to substitute for sewing, is only applicable to the soles and heels of boots or shoes, all the other parts being made in the usual manner. The *last* which is used for this method is the only implement which demands a particular description. It is first made in wood, of the same figure as the common last, and adjusted in the usual manner to the size and shape of the shoe which is intended to be made or put together upon it. The lower part or sole of the last is then covered with a plate of iron or steel, about the same thickness as a stout sole leather: this plate, being formed to the exact shape which is desired, is fastened down upon the wood by serews or rivets. The iron plate has three circular holes made through it, one at the toe, another about half way between the toe and the heel, and a third at the heel: the holes are about an inch in diameter, and being filled up with wooden plugs, and cut down even with the surface of the iron, they will admit the points of temporary nails to be driven through the leather sole to penetrate into the wood, and fix the sole upon the last whilst the work goes on.

The making of the shoe is conducted in the usual manner, until it is ready for putting on the last. To do this, the inner sole is put upon the iron sole of the last; then the upper-leathers are put upon the opposite part, and the edges of the leather are turned down over the edges of the inner sole: the outer sole is then applied over the turning-down, and fastened in a temporary manner upon the last, by driving one or two nails, through both soles, into the wooden plugs before mentioned, which fill up the holes in the iron face of the last. Now, to unite the two soles to the upper-leathers, holes are pierced all round the edges of the sole, and small nails are driven in, which are of sufficient length to penetrate through the sole and the turning-in of the upper-leathers, and also through the inner sole, so as to reach the metal face of the last, and being forcibly driven, their points will be turned by the iron, so as to clench within, or rivet through the leather, and serve instead of the sewing or stitching commonly employed to unite the sole to the upper-leathers.

## SHOES.

SHOES, *Machines for making.* These are the invention of Mr. Brunel, of whose mechanical genius we have had frequent occasion to speak in this work. He has lately established at Battersea an extensive manufactory of shoes, chiefly intended to supply the army, where all the operations are performed by the aid of machines, which act with such facility, that they can be managed by the invalid soldiers of Chelsea Hospital, who are the only workmen employed, and most of them disabled by wounds, or the loss of their legs, from any other employment.

The shoes made by these machines are different from the common shoes, in the circumstance of the sole being united to the upper-leathers by a number of small rivets instead of sewing, in the same manner as those we have mentioned in the preceding article. To facilitate the description we intend to give of the machines, we shall first describe the structure of one of these shoes. Its upper-leathers are the same as any other shoes, and consist of three pieces; *viz.* the vamp, or part which covers the upper part of the foot, and the two quarters which surround the heel, and are sewed together behind it; they are also sewed to the vamp at about the middle of the length of the shoe. The sole part of the shoe is composed of the real or lower sole, with its welt, the heel, and the inner or upper sole.

The lower sole has an additional border, which is called the runner, or welt, fixed upon its upper side, all round the edge, by a row of rivets, so that it makes a double thickness to the sole towards the edge; but this additional piece is only of small width from the outside of the sole inwards, and gradually diminishes away in thickness to nothing, as it recedes from the edge of the sole, so that the middle part of the sole is only of the same thickness as the single leather. The upper-leathers are made sufficiently large to turn in, all round, beneath the foot, under the edge of the inner sole, for about three-quarters of an inch wide, and the outer sole, reinforced by the welt, is applied beneath, so that the turning-in is included between the two soles; that is, it is included between the edge of the inner sole and the welt, or extra thickness which surrounds the lower sole. To hold the shoe together, a row of rivets is put through the sole, all round the edge, and they are of sufficient length to pass through all the four thicknesses, *viz.* the lower sole, the welt, the upper-leathers, (where they are turned in,) and also through the inner sole; and these rivets being made fast, unite the parts of the shoe together in a much firmer manner than sewing. The rivets have no heads, but are made tapering, and the largest ends are on the outside of the sole, which prevents them from drawing through; and at the same time, the strength of the rivetting will not be materially impaired by the gradual wearing away of the sole leather.

These rivets prevent the wear in a very great degree, and for this reason there is a greater number of rivets put into the sole than merely those which hold the shoe together. The different nails are, first, the *short nails*, or rivets, which only penetrate through the single thickness of the lower sole; these are arranged in parallel rows across the tread of the foot, that is, about two-thirds of the length from the heel; there is likewise a double row of short nails, which is carried round parallel to the outline of the toe, at about three-quarters of an inch from the edge, and extends as far as the middle of the foot. Next, the *tacking nails*, which are of a sufficient length to reach through both the sole and the welt, and thus fix the two together: of these, there is a row all round the edge of the foot, nearer to the edge than the row of short nails before mentioned. Lastly, the *long nails*, which, as before described, fasten the shoe together: these form also a complete row round the edge of the

whole shoe, and nearer to the edge than any of the preceding rows. The heel is also fastened on by a row of long nails round its circumference. The heads or thick ends of all these nails appear on the lower surface of the sole, and all contribute to preserve the leather from wearing. We shall now proceed to a description of the ingenious instruments and machines used in this manufactory, beginning with those for

*Cutting out the Leather.*—This is performed by stamps, each of which is an iron frame or ring, bent to the size and figure of the sole, or other part to be cut out by it: one edge of the frame is edged with steel, and ground sharp, so that it will cut the leather: the sharp edge of this frame being placed upon the skin, and struck with a mallet, will cut out a piece from the skin, which is exactly of the same size as the interior opening of the frame. The leather for the soles is first softened, by soaking it in water; the skin is then spread out on a block or table of lead about two feet long and eighteen inches wide, and the stamp or knife for the soles is placed upon the skin in the most advantageous position to cut out the piece; then two or three blows upon the top of the knife with a beetle or large wooden mallet, forces its edge through the leather, and cuts out the piece, which remains in the opening of the knife, but being taken out another is cut in a similar manner.

A knife of this kind is provided for all the pieces which are used to form the shoe, and they are called after the names of the respective pieces, which are as follow: 1. The sole, which is not cut out the full size for the sole of the shoe, but wants a piece at the heel. 2. The sole-piece is a semi-circle, to be joined to the sole to make up the heel. 3. The heel: these two last pieces are cut out of the small pieces, or scraps of leather. 4. The runner, or welt, which is applied upon the sole, all round the edge, to make the extra thickness where the upper-leather is to be joined to the sole. All these parts are cut out from the strong hides. 5. The inner sole. The upper-leathers are, 6, the vamp, or part which covers the toes and upper part of the foot; 7 and 8, the right and left quarters, which surround the heel, and are sewed to the vamp, being also sewed together behind the heel.

All these parts, except the welts, are cut out by knives of the above description, there being a set of knives for every different-sized shoe which is made in the manufactory. For cutting out the inner soles, the knife is fixed horizontally, with its edge upwards, beneath a heavy cast-iron lever, which moves on a centre pin, supported in the same framing which sustains the knife. The lever has a plate of lead attached to it near the centre, so that when it is brought down horizontally the lead will descend upon the knife, the edge of which being imprinted into the lead, will cut through the leather which is previously spread upon the knife. To use this cutting-out machine, the sole is first cut out roughly from the skin by a common cutting-knife round a wooden pattern, and the lever being lifted up nearly to a vertical position, the rough sole is laid fairly upon the edge of the knife; then, by letting fall the lever, its weight, and the leverage upon the plate of lead, causes a sufficient pressure upon the leather to force it upon the edge of the knife, and cut it to the exact shape required. The lever is guided in its descent, to ensure that its lead shall fall precisely upon the knife.

Immediately after the soles are cut out, they are stamped on the grain-side of the leather with a number which denotes the size of the shoe to which they belong. The stamp is engraved on the face of a small hammer, so that one blow makes the desired mark. The heels and other parts are also marked,

marked, that the workman may make no mistakes in putting the shoes together.

The leather for the welts is cut into strips of about an inch wide: for this purpose, the piece is spread on a flat table about two feet square, the surface of which is covered with small iron rulers the width of the intended strips, and screwed down upon the wooden table, leaving between them sufficient spaces to admit the point of a knife. Several small pins project up from these iron rulers to penetrate the leather and hold it fast. To confine the leather down whilst it is cut, a frame of iron is fixed to the table by hinges at one end, so as to fold down horizontally upon the leather; and the frame is covered all over with similar rulers, the intervals between them corresponding exactly with those between the rulers on the table. The cutting is performed by a hooked knife, fixed into a long handle. The workman holds down the frame upon the leather, and introducing the hooked point of the knife between the bars, draws it towards him; this cuts through the leather, and he repeats it at every interval between the rulers, and thus divides the whole leather into slips of the same breadth as the rulers.

To prepare these slips for use, each one is split lengthways into two other slips, by an oblique cut along the middle of it; thus producing two slips, which have bevelled or feathered edges, similar to a ruler for drawing. The splitting of the strips is performed by a very complete machine, consisting of a pair of brass rollers, one of which is turned by a winch, and the other receives its motion from it by means of a pair of equal cog-wheels, one wheel being fixed upon the ends of each of the rollers. The rollers are mounted one above the other in an iron frame, in a similar manner to those used for laminating: the lower one has a groove formed round it, which is of a proper size to receive the strip of leather before it is divided, and the pressure of the upper roller compresses it into the groove. A guide, consisting of an iron stem, with a square hole through it, is fixed up before or in front of the rollers, to conduct the leather into the groove; and on the opposite side, or behind the rollers, is a stem, or standard, which receives a cylindrical steel pin, and holds it fast in an horizontal position, in the direction in which the strip of leather will move when it comes through the rollers. The end of this steel pin is flattened and ground to a fine sharp edge, like that of a chisel, and presenting itself to the end of the strip of leather as it is passed through the rollers, will evidently divide the strip longitudinally into two pieces, when the leather is forced forwards against the edge of the cutter by the motion of the rollers. This edge is placed obliquely to the axis of the rollers (or to the surface of the leather which passes between them), and therefore will divide it by an oblique cut, so as to produce two narrow feather-edged pieces from each strip. The pressure of the rollers upon the leather tends to consolidate its texture, and supply the place of hammering.

*Preparation of the Soles.*—The leather is hardened by passing it between rollers, to produce the same effect as hammering does in the ordinary method of shoe-making. The rollers used for this purpose are made of brass, about five inches diameter, and as much in length; they are mounted in the usual kind of frame, except that instead of screws to hold down the upper roller, and regulate its distance from the lower one, two plain cylindrical pins are inserted into the holes which usually receive the screws, and these pins have a strong lever bearing upon their upper ends, to press the upper roller down upon the lower, by the action of a weight at the extremity of the lever. These pins are only about four inches distant from the centre or fulcrum of the lever, and the weight (of about 100 pounds) is at a distance

of four feet from the centre, it therefore presses down the upper roller upon the lower, with a force of nearly 1200 pounds. The lower roller has a cog-wheel upon the extremity of its spindle, which is moved by a pinion upon the end of an axis turned by a winch; one man turns this winch and another puts the soles between the rollers. Two soles are presented together, being laid one upon the other, with the flesh sides of the leather towards each other, and an iron plate is placed between them, which is made thick in the middle, and diminishes every way to the edges, where it is thin. The grain or hair side of the leather of the two soles is outside, so as to be in contact with the rollers when the soles are presented to the machine which draws them in; and when they have nearly passed through, the man who turns the winch reverses the motion, and rolls them back again, then forwards, and so on for four or five times, in the same manner as the motion for mangling linen. After this operation the leather becomes hard and solid, and much reduced in thickness, particularly at the middle part.

The heels being so small cannot conveniently be rolled; but to produce the same effect they are stamped in a fly-press: for this purpose, a heel-piece is put into a small box or cell of cast-iron, of a proper shape to receive it, and a thick plate, which is fitted to the box, being laid upon it, the whole is put beneath the screw of the press, one blow of which is sufficient to press the iron plate upon the leather, with a force which will render it hard and solid.

The sole is made complete by joining to it the small semicircular piece at the heel; for this purpose, the parts which are to be joined together are cut bevelled, so that they will overlap without increasing the thickness, and then three or four nails are driven through the bevelled parts, to hold them together. To cut the joints bevelled, a simple press is used; the sole is laid flat upon the edge of the bench, and a piece of iron is pressed down upon it by a lever, upon which the workman leans his elbow. The edge of the bench is bevelled, and faced with iron, and this, together with the upper piece of iron, guides the knife, so that it will cut the joint bevelled: the heel-piece is then cut in the same manner, but reversed.

*Application of the Short Nails.*—The leather for the sole is next inlaid with short copper or iron nails, which are put through holes in the leather, in the broad part of the foot, where the greatest wear will take place; and there is also a double row of similar rivets, inlaid round the toe part, at about three-quarters of an inch within the edge of the sole. The holes for these nails are first punched in the leather of the sole by a punching machine, and then a second machine cuts the nails, and inserts them into the holes.

The *punching machine* is moved by the foot of the workman, who is seated before a small semicircular table of cast iron, on which he places the leather. This table is supported by a strong column, rising from the floor to a height of about two feet above the table, which is joined to the column by a projecting bracket, so that the column is on the opposite side to that where the workman is seated. The upper part of the column has two arms, projecting forwards from it towards the workman, and extending over the table; at their extremities they are formed into sockets, to sustain a square iron rod or perpendicular slider, which at the lower end has the piercer or awl screwed into it: one of the sockets guides the upper part of the slider, and the other the lower part, so that it has a freedom of motion in a perpendicular direction, but no other. The slider is caused to descend by means of a treadle moving on a centre pin, attached to the foot of the iron column, beneath the bench; from this treadle an iron rod ascends through a hole in the

## SHOES.

bench (and also through holes in the arms, which project from the column to sustain the slider), and at the upper end this rod is connected with a lever, which moves on a joint at the upper end of the iron column, whilst the extreme end of the lever is connected with the top of the perpendicular slider. By this arrangement it is clear, that the foot, being pressed upon the treadle, will communicate motion by the iron rod and upper lever to the slider and piercer, and force its point through the leather, which is placed upon the small iron table. A short lever and counterpoise are provided to raise up the slider again the instant the pressure is removed. To prevent the piercer striking upon the iron of the table, and breaking the point, a screw is inserted in a piece projecting from the slider, and its point in descending comes to rest upon the upper of the two arms which sustain the slider, and thus stops the descent of the slider at the proper place.

The piece of leather for the sole is fixed upon a pattern made of iron plate, cut to the same size and shape as the sole, which is united to it by two sharp gauge pins, which are fixed in the pattern, one at the middle of the tread, and the other in the centre of the heel; and these pins project so far, that they will just penetrate through the leather, to hold it fast against the pattern, which is perforated with all the holes which are intended to be pierced in the sole. The leather is applied upon the pattern, and struck with a mallet, so as to force the gauge pins into the leather, and unite the sole and the pattern together; the pattern is then laid flat upon the table of the machine, with the leather uppermost, and is brought beneath the joint of the piercer, so that it will penetrate in the desired place. To ascertain this place, a small stud or pin is inserted into a hole in the table, in the exact spot where the point of the piercer descends; the stud projects a little above the surface of the table, but is only held up by a spring, so that it can easily be pressed down. The pattern being placed so that any of the holes therein receive the point of the stud, it is evident that when the pressure of the foot makes the piercer descend, its point will make a puncture in the leather which is fastened upon the pattern, which puncture will be opposite to the hole in the pattern; and though it perforates the leather quite through the thickness, the point of the piercer cannot be blunted against the iron, because it is received in the hole in the pattern, and the stud descends by the pressure, so that the pattern will lie quite flat upon the surface of the table. In this manner the workman pierces any number of holes in the leather, placing it beneath the point of the piercer by the aid of the pattern, and then pressing the foot to bring the point down and pierce the hole. As soon as the piercer rises, he removes the pattern to another hole, and so on. A small piece of iron is fixed just above the leather, which prevents its being lifted up, and following the piercer when it rises. The piercer passes through a hole in this piece.

*Nailing Machine for the short Nails.*—The sole being thus pierced with holes, the short nails are put into it by a very curious machine, which at the same time forms the nails, by cutting them off from the end of a strip of iron or copper, of the same breadth as the length of the intended nails.

The sole is presented to the machine by laying it upon a small table, similar to the last machine, and is directed by means of the same pattern; so that each of the holes in the leather will be successively brought beneath the point of a blunt piercer, which descends by the action of a treadle. In the upper part of the machine is a pair of shears, to cut the nails: they consist of a lever, loaded at the extremity with a weight, and connected with the treadle, so that the end of the lever is lifted up when the treadle is depressed by

the foot. Near the centre of this lever is a cutter, which is fixed to it, and moves with it. Another cutter is supported by the frame, so as to be stationary, and in the proper situation to come in contact with the edge of the moving cutter, when the end of the lever is lifted up. The cutters act in a manner similar to a pair of shears, to cut off a small piece from across the end of a slip of iron, which is introduced between the cutters. This piece forms the nail or rivet, which is to be put into the hole in the leather; and immediately after it is cut, it falls into a tube, by which it is conducted down to a small cell or tube, situated immediately over the leather. In this the nail stands perpendicular, and ready, when the piercer descends, to be forced down into the hole in the leather; because the cell which receives the nail is exactly beneath the point of the piercer, so as to hold it perpendicularly in the proper situation. The workman is seated before the machine, and with his right hand directs the sole, with its pattern beneath the piercer, in the same manner as before described. In his left hand he holds the strip of iron or copper which is to make the nails; and he introduces the end of it through a small hole, which conducts to the cutters, pushing it forward with a gentle force: this causes the end of the strip to enter between the cutters, when the shears are open. Then adjusting the sole by the pattern, so that one of the holes in the leather will be beneath the nail contained in the cell, he presses down the treadle: this forces the nail down from the cell into the leather, by the descent of the piercer, and at the same time closes the shears, and cuts off a nail across the end of the strip. The nail immediately descends by the tube into the cell, where it places itself perpendicularly, and ready to be put in its place in its turn. Thus the machine, at every stroke, cuts a fresh nail to supply the place of that which it puts in the leather by the same stroke. The strip of copper is turned over every time, to form the nails alternately head and point.

When all the nails are put in, they are hattered down with a hammer; and as they are but very little longer than the thickness of the sole, this reduces them to an even surface.

*Application of the Welt to the Sole.*—The welt, or runner, is a narrow slip of leather applied upon the sole, round its edge, to make the sole of a double thickness round the edge, where the upper leather joins to the sole, although the sole is only single within. The welt is made from the feather-edged slips which we have before mentioned, and is fastened to the sole by tacking nails of sufficient length to pass through both the sole and the welt. These nails are arranged all round the circumference of the sole, and the holes are first pierced through the sole by the punching machine, which we have before described, but by a different pattern of iron, which is attached to the sole by its two gauge pins entering the same holes which were made through the leather in the first operation. This pattern is pierced with a row of holes all round the circumference, which are arranged within the former row of rivets, or farther from the edge of the sole; but around the toe and tread of the foot, for half its length, the holes are in double number, or at half the distance that they are in the heel part. This pattern being used in the same manner as before described, the punching machine pierces the sole with holes, exactly corresponding to it; which holes are filled with tacking nails in a separate machine, something similar to the nailing machine before described. But as the nails are longer, it would be too laborious to cut them by the same motion; the nails are, therefore, cut by a machine made on purpose, and applied to the leather by

## SHOES.

*The nailing Machine for long Nails.*—This is made exactly the same as the punching machine before described, but with additional apparatus to supply the nails, and put them into the holes. Thus it has a vertical column, with a table and two projecting arms to support the perpendicular slider, which is caused to descend when the foot is applied upon the treadle, and to re-ascend by the action of the counter-weight. The piercer at the lower end is not sharp-pointed, not being intended to penetrate the leather, but only to force the nails into the holes previously pierced by the preceding operation. The additional parts are as follow: a circular plate, or wheel of brass, about nine inches diameter, and of a thickness nearly equal to the length of the nails; it is perforated with a great number of holes, to contain the same number of nails; the holes being made round its circumference, as close together as convenient, and arranged in four circles, one within the other. The interior space within the circles is formed with six arms, like a wheel; and in the centre is a hole, which fits loosely upon an upright centre pin, standing in the centre of a small circular table, which is fixed sideways to the upper of the two arms, which, as before mentioned, project from the vertical column of the machine, and sustain the upper end of the perpendicular slider. Upon this circular table the wheel is supported in a horizontal position, at the height of 18 or 20 inches above the table on which the leather is placed, and with liberty to turn upon its centre pin. The wheel is filled with nails when it is used, one being put into every hole of its circumference, with the points downwards; and the holes are sufficiently large to let the nails drop through the wheel, except when their points rest upon the circular table which supports the wheel. At one part of the circumference of this table an opening is cut through it, and a small tube descends from it, to conduct a nail down to the point of the piercer. The motion of the wheel upon its centre brings the nails successively over the opening or mouth of the tube; and therefore each nail, in its turn, drops by its weight through the hole in the wheel into the tube, which is made so small, that the nail must descend with its point downwards, and fall into a small cell, so situated that the nail will stand exactly beneath the point of the piercer, when the same is at its highest position. But when the piercer is depressed by the action of the treadle, its point will act upon the head of the nail, and force it down through the cell into the leather placed upon the table of the machine; the hole in the leather having been previously pierced by the punching machine. The cell which receives the nail is very ingeniously contrived to hold it in a perpendicular direction, beneath the end of the piercer. It is situated immediately above the leather, and is conical within, so that the nail drops down into it until it becomes fixed fast; but when the nail is to be forced down by the piercer, the cell opens in two halves, being formed by notches in two pieces of steel, which are only held together by being screwed together at one end, and are made so thin as to spring together, and form a cell for the reception of the nail, although they will readily separate when the piercer forces down the nail. It is during the ascent of the piercer that another nail is dropped down from the wheel through the tube, and received into the cell, whilst its two halves are still kept open by the piercer; or rather as the piercer at this moment occupies the interior of the cell, the nail is received in the space, or open joint, at which the two halves of the cell separate, so that the nail lies close by the side of the piercer. But when the piercer has risen up completely out of the cell, its two halves spring together, and the joint in which the nail is placed being formed with faces inclining

inwards, they throw the nail into the cell itself, in which it drops down till it sticks fast; because, as before stated, the cell is smaller at the bottom; and in this situation the nail is certain to be held perpendicular, with its head under the point of the piercer.

To turn the wheel round, so as to supply a fresh nail every time that one has been put into the leather, the edge of the wheel is cut into ferrated or sloping teeth; the number of teeth being equal to the number of holes made in each of the four circles to contain the nails. A small detent or click takes into these teeth by a hook, so that it will turn the wheel when moved in one direction, but slide over the teeth when moved in the other direction. The click is jointed to a short lever, fixed upon the upper end of an upright axis, which passes down through the two projecting arms of the main column, so as to be very near the perpendicular slider; and a short lever, fixed to this axis, bears, by the action of a spring, against a wedge fixed to the slider. The action of this mechanism is to turn the wheel round one tooth at a time: thus, when the slider descends, its wedge forces the end of the short lever farther away from it; this movement is communicated by the upright axis and upper lever to the click, which slides over the sloping sides of the teeth of the wheel; but on the re-ascent of the slider, the wedge allows the lever and click to return by the action of a spring, and the hook of the click, having caught a tooth of the wheel, will turn the wheel round the space of one tooth. In this manner, at every descent of the slider the click engages a fresh tooth of the wheel; and at every ascent, the wheel is turned round upon its centre pin; the weight of the wheel, resting upon the flat circular table, being sufficient to retain it as it is placed.

The nailing machine acts with the same rapidity as the other machines, to put a nail into every one of the holes previously made; and for this purpose the leather is kept upon the same pattern by which those holes were pierced, not only for the purpose of placing the leather so that the nails shall be inserted into those holes, but that the thickness of the pattern may allow the nails to penetrate and project through the leather on the under side. When the nails are all put in, they are beat down with a hammer, to drive all the heads to a level with the surface. The leather is then separated from the pattern, and put into a frame called

*The welting Stand.*—This machine is a small square table of cast-iron, fixed on the top of a pedestal, in which it is capable of turning round, for the convenience of the workman, and to enable him to work at the different sides, as he remains seated before the table. An iron frame is connected with the table by hinges at one side, so that it can be lifted up or turned down, to lie flat upon the surface of the table; and in this situation it can be fastened down by means of a simple clamp. This frame is intended to hold fast the leather which is placed beneath the frame: the interior opening of the iron frame is nearly of the same size and shape as the sole of the shoe. The sole is placed flat upon the table, in the proper position, which is determined by two gauge pins fixed into the table, and entering the holes made in the sole; then the iron frame being turned down upon the leather, will inclose the sole as it were with an iron hoop, or railed border, all round the edge; and the frame being clamped fast down, the sole is confined, as if lying in the bottom of a cell of iron, of the same figure as itself, and with the nail points projecting upwards from the sole. In this frame the welt is applied, by laying the strip of leather upon the edge of the sole in contact with the inside of the iron frame, and bending it to follow the curves of the outline of the sole. As fast as any part of the length of the

strip is settled to its position, it is attached to the sole by striking it down with a mallet upon the points of the nails. The thin or feathered edge of the strip of leather is put inside, so that the edge of the sole, for about the breadth of half an inch, is of a double thickness; but within this, the extra thickness diminishes away to nothing, leaving only the thickness of the sole. The ends of the strip of leather which compose the welt, where they join and complete the circuit of the sole, are cut sloping, so as to lap over each other, and make a joint, without any increase of thickness, or apparent division. When the sole is taken out of this frame, the welt and sole are beat well down together, to make a good joint; it is then carried to the cutting press, in which the edge or outline of the sole and welt are cut smooth, and to the same size; because, as the frame of the welting machine must be rather less than the sole, in order that the frame may bear upon the edges of the sole all round, and thus hold it fast, the welt, which is moulded or bent round within the frame, will be a small quantity less all round than the sole. To guide the knife in cutting round the edge of the sole, it is confined between two iron patterns, which are made exactly to the size to which the edge is to be pared. They are attached to the sole by two gauge pins, fixed into one of the plates, and passing through the holes in the sole, project far enough on the opposite side for the other plate to be fastened on, in its required position, by two holes which receive the ends of the pins.

The *cutting-press* very much resembles a common lathe: a horizontal spindle is supported in a frame, consisting of two standards, erected from a horizontal plate, to sustain the spindle, which passes through a collar in one of these standards, and projects some inches beyond it, having at the extremity a piece of wood flat on the surface, and of the same shape as the sole. Against this flat surface the two iron plates, with the sole between, are placed, and they are forcibly pressed together by the action of a screw, fitted into a third iron standard, erected from the same horizontal plate, and pressing by means of a lever upon the iron plates exactly opposite the end of the spindle. This pressure causes the spindle to retreat a small quantity in the direction of its length, and then a flat circular plate, fixed upon the spindle, (in the same situation as the pulley of a common lathe,) is made to press against a similar flat plate, which is fastened to the frame, and therefore cannot turn round. By the friction between these two surfaces, the spindle becomes immovable, and the press holds the sole firm, whilst the workman, who is seated before the machine, cuts all round the edge with a drawing-knife, which is made sharp in the middle, and is worked with both hands by having a handle at each end. When he has with this tool pared down that part of the edge which is uppermost, he releases the screw of the press, and a spring then causes the spindle to advance so far as to relieve the flat circular plate, which is fixed upon the spindle, from its contact with the fixed plate. This leaves the spindle at liberty to be turned round, and the sole turns with it, so as to bring up a new part of the edge of the leather to a convenient situation to be pared or cut; and the screw is then turned to fasten the spindle as before described, and at the same time to press the sole between the two patterns.

When the edge of the sole is thus cut, it is carried to a grindstone, and ground smooth: the stone is turned with a quick motion, by means of a band and large wheel; the leather is afterwards polished by applying it to the edge of a wooden wheel, on which a little bees-wax is spread.

*Application of the long Nails.*—The sole, thus re-inforced by the welt, is returned to the punching machine, and be-

ing attached to another pattern, a range of holes is pierced all round the outer edge, through both, just within the former row of tacking nails; after which, by the nailing machine, these holes are filled with nails which project through the upper side of the welt, being longer than any of the former, and being also intended to penetrate through the upper-leather and inner soles, and thus fasten the shoe together. In this state the sole is ready to be put to the upper-leathers.

The *upper-leathers* are prepared for applying to the sole, in the same manner as the ordinary shoe, *viz.* by sewing the vamp, or piece which covers the upper part of the foot, to the two quarters which go round the heel, and also sewing these two quarters together behind the heel. The workmen do not hold the work upon their knees to sew it, but four men work at a square table, the corners of which are cut off, and a small piece of wood projects from each angle: the two pieces of leather which are to be sewed together are laid upon one of these pieces of wood in the proper position to be sewed, and are held fast by an endless strap, which is laid over them, and the workman binds it fast down, by pressing his foot in the strap, like a stirrup. This method of sewing, which is far superior to the common mode, might, from its simplicity, be used by all shoe-makers, and would render their business less unhealthy; whereas at present they are subject to many diseases from sitting in the awkward and unnatural posture which is necessary to reach their work, when they hold it upon their knees.

*Operation of closing or rivetting the Shoe together.*—The upper-leathers are put upon a last, and held tight thereupon whilst the sole is applied. This is done in

*The Clamping Machine.*—It is a small oval table, supported on a column, but capable of turning round upon the column, to enable the workman to work at any side. In the centre of the table a last is fixed, with the sole upwards; it is supported at a height of about six inches from the table. The sole is made of cast-iron, in a solid piece, with the stem or part by which the last is supported; but the under part, upon which the upper-leathers are to be moulded, is made of wood, for the convenience of altering the figure when necessary. The last is fixed upon the table by means of two steady pins; and a strong pin, which projects from the lower part of the last, and passes through the table, is bound fast by a wedge, which confines the last firmly upon the table, in the same manner as if it was made in a piece therewith. The table has a number of pieces of brass attached to it by hinges, and arranged all round the last in such a manner, that they can be turned up against the lower part of the last, and then form clamps, which are exactly adapted to the figure of the lower part of the last, and will therefore clamp or bind the leather firm upon the last at the toe, heel, and every part thereof, except at the flat part of the sole. The brass clamps are of such dimensions, that they will touch each other when turned up, and thus form a complete cell or box, in which the lower part of the last will be contained, and the leather confined upon it; but the cell being made in several pieces, or clamps, they can be removed one by one, as found necessary. The clamps are forced up to their situation by means of an independent screw for each, which is tapped in an oblique direction through the edge of the table, and the point forces up the end of a small rod, which is jointed to the clamp near the part where it acts upon the leather: by this means the force of the screw acts to turn the clamp up upon its hinge, and at the same time presses it against the leather. When the pressure is released by displacing the end of the small rod from the point of the screw, the clamp will be suffered to fall back upon the table; and this being done

done to all the clamps, the last stands insulated in the middle of the table, from which it can be detached by withdrawing the wedge which confines it. The inner sole of the shoe is first put upon the sole of the last, being slightly fastened thereto by two short pins, one of which is driven through the gauge hole in the toe of the sole, and enters a hole made in the last; and the other pin is fixed in the heel part of the last, and enters the hole in the sole. The upper-leathers are now put upon the last in the true position. In this state, the last is taken to the clamping machine, and fastened into its place in the centre of the table; the clamps are then turned up, one by one, beginning at the heel, and the upper-leathers being pulled up all round by a pair of pincers, so as to make them fit tight upon the last, the clamps are screwed tight. In this state, the upper-leathers are made to take the form of the last, being firmly attached thereto, except at the sole part: at this part the leather stands up all round about three-quarters of an inch, which quantity is turned down flat upon the edge of the inner sole (previously fastened upon the sole of the last), and a small quantity of paste is put in to make it stick fast: four or five notches are cut out in the leather at the toe and at the heel, to make the part which is turned down lie flat upon the sole, without folds or overlapping, and then, to make a close contact, the leather is beaten down. Parings of leather are likewise passed, and stuck flat upon the inner sole for levelling, to make up the sole to the same thickness in the centre as it acquires towards the edges all round by the turning-in of the upper-leathers. In this state, the nail which fastened the inner sole to the last is withdrawn, being now unnecessary, and the real sole is applied, an iron frame, or saddle, being employed to determine its proper position upon the last. This frame is made of thin iron, and its figure within is similar, and of the same size as the row of nails which project through the sole, and by which the sole is to be rivetted into its place: it is made in two halves, which are united by a joint or hinge at the heel part; and at the toe part are two holes, through which a pin can be put to hold the frame together. This pin, as well as the joint pin of the hinge at the heel, projects downwards sufficiently to enter into a hole made in each of the two clamps at the toe and heel, in such a position as to guide the frame, so that it will apply the sole exactly in the proper position.

The sole, when prepared as before described, by inserting all the long nails in the holes, so that their points project through the leather, is put into an iron box or mould, and a plate being laid upon it, is put into the fly-press, and by a single blow the sole is rendered concave within, so as to adapt itself to the last. When it is taken out of the mould, the iron frame before-mentioned is put together round the row of nails, the size of the inside of the frame being made exactly of the proper size to receive the projecting points of the nails, and retain them perpendicular to the leather, and prevent them from spreading out. The sole is then applied in its place by the two guide pins of the frame, and by striking upon the heads of the nails, their points penetrate through the turning-in of the upper-leather, and also through the inner sole. When they are well entered the iron frame is taken away, by withdrawing its pins, and opening its two halves on their joint, and the nails are driven down into their places. This causes them to project through the inner sole into the shoe, and the points meeting the iron last are turned back, and thus clenched into their places. To render this more certain, the sole of the last is made with a slight groove all round, where the points of the nails will fall, and the groove

being of a semicircular figure, the points are more readily turned thereby, and are all turned the same way, so that they will not interfere.

The shoe is now put together, and the clamps being relieved and turned down, the shoe is taken off the last; for which purpose the heel of the last is made in a separate piece, and jointed to the other by inclined fittings, and with a tongue or rebate, so that it can be held fast in its place by a single hook or spring catch; but this being relieved, the shoe draws off the last with the greatest ease, the heel part remaining within the shoe, and is taken out afterwards. The shoe is now carried to the *rivetting last*, where it is put upon a last exactly similar to that of the clamping machine, but fastened down upon a bench, and the sole is smooth without the groove, which caused the points of the nails to turn up. Upon this last the nails are beaten down, to rivet all fast, and make the sole smooth within: the heel is then put on by laying it in its place, and driving down the long nails which have been put through it by the nailing machine, in the same manner as for the sole.

The sole of the shoe is now rasped with a coarse file, to level all the nail-heads, and render the leather smooth; the shoes are then carried to the grindstone, by which they are polished, and finished up in every part, the soles blacked, and polished by the wheel with a composition of bees-wax and ivory black, which renders them glossy: the upper-leathers are then brushed by a circular brush, which is turned by the lathe, and the shoes are rendered fit for sale, except those which require binding and lining, with a lining of thin leather, in which case they are finished in the same manner as common shoes.

*Nail Machine.*—This is equally deserving of notice with any other part of this ingenious manufactory. In our article *NAIL* we have described some nail machines; but we consider this as a much better machine for cutting brads or nails without heads. The nails are cut from sheet-iron, the plates being first reduced into slips, of a breadth equal to the length of the intended nails, by a large pair of shears, acting in the same manner as those described in the article *CANTEN*, but are constructed in a superior manner, by employing cast-iron for the framing and for the lever. The iron plate is presented to the machine by one man, whilst another works the handle, and at a single stroke cuts off the desired strip of iron: the sheet of iron is cut so that the direction of the grain, or fibrous texture which the iron acquires by rolling, will be across the length of the strip. From this it follows, that when the nails are formed by cutting off narrow pieces from the end of the strip, the grain of the iron will be the lengthwise of the nail.

The *cutting of the nails* is readily performed by the machine, which is turned by the foot of the workman, whilst he supplies the iron by his hands. The motion of the treadle turns a crank and heavy fly-wheel, similar to the wheel of a lathe: from the same crank a rod proceeds to the longer end of a stout lever, the axis of which is supported on pivots in the upper part of the frame, so as to be above the wheel and crank. At a small distance from the centre of the lever, and at the opposite side of the axis to the long lever, a steel cutter is fixed, which acts against a fixed cutter supported by the frame; the fixed cutter has an edge on the upper side, and the moving cutter, which is fixed to the lever, is made sharp on the lower side. The revolution of the wheel and crank causes the lever to rise and fall, and the edges of the two cutters in this motion pass as close together as possible, without touching. At the most elevated position of the moving cutter, its edge rises above the edge

of the fixed cutter so far, that the thickness of the strip of plate can be admitted between them; the end of the strip is pushed back, so that a small portion of the end of it overhangs the edge of the fixed cutter; therefore the edge of the fixed cutter, when it descends, meets this overhanging piece, and pressing it down upon the edge of the fixed cutter, cuts it off, and the piece so separated forms a nail. When the moving cutter re-ascends, the iron is pushed forwards again to overhang the fixed cutter, and another nail is thus cut off. The nails are narrow at one end to form the point, but at the other end are about as broad as the thickness of the plate, so as to be of a square figure; but at the point they are, in one direction, as broad as at the head; this is the direction of the thickness of the plate, so that in reality the nail is the figure of a small wedge instead of a pyramid, the point being in fact a sharp edge. To effect this, the cut which the machine makes across the end of the strip of iron is not perpendicular to the length of the strip, but rather inclined thereto; and at every successive nail which is cut, the inclination of the cut is reversed, so that the head of one nail is cut from the same side as the point of the next, and so on alternately of the whole length of the slip of iron. The thickness of the nail is regulated by the quantity which the end of the slip is allowed to project over the edge of the fixed cutter, and the angle of inclination by two stops, against which the edge of the slip is always brought to bear, when the workman places it ready for the cut. To stop the end of the iron, a part projects from the lever beneath the edge of the moving cutter, and is curved to the arc of a circle described from the axis: this stop is as far removed behind the edge of the cutter as the thickness of the nail intended to be cut off by the descent of the moving cutter. In working the machine, the workman keeps the wheel constantly revolving by the motion of the treadle; and holding the slip with its edge in contact with the two stops, so as to give it the proper inclination, he pushes it forwards, with a gradual pressure, against the moving cutter: then the instant the cutter is sufficiently raised to admit the slip, it will advance forwards, until the end of the slip touches the stop which is beneath the cutter: on the descent of the cutter, the nail is cut off, and the workman immediately turns the slip with the other side upwards, which has the effect of reversing the inclination of the cut; and pushing it forwards, another nail is cut as the former, and thus the operation continues with the utmost rapidity.

There are several suits of machines in this manufactory, so that a great number of shoes are proceeding at the same time through the different stages of their fabrication; and the rapidity of the execution is such, that a given number of workmen will here make a far greater number of shoes than by the common method, and they are more durable, particularly for the strong shoes which are desirable for soldiers. Several of the machines were constructed by Mr. Maudslay, with his usual accuracy of execution.

*Shoe-makers' Machine.*—This is a simple contrivance, to enable those artificers to perform their work in a standing posture; by which means they will avoid the diseases incident to those who follow sedentary employments.

In the common method of working, the shoe-maker is obliged to sit and stoop in the most awkward posture imaginable, sometimes in order to hold the shoe and last between his stomach and his thigh, whilst he sews the sole to the upper leather; at other times he must hold the last between his knees; and to sew the leathers together whilst he holds them upon his knees, he must lean very much forwards. In all these operations he sits as it were doubled up, so as to

impede the action of his lungs, and ultimately produce many diseases. The machine is a kind of vice, to hold the shoe in any position whilst it is sewed.

The Society of Arts have shewn a laudable desire to recommend these machines to the trade; and to induce their general adoption, they have given several rewards to those who have produced machines. The first of these was Mr. Holden, then Mr. Parker, and next Mr. Stafs, whose machine, being more improved than the preceding, demands some description. A small bench, or table, is firmly supported on four legs, at about four feet from the ground; a circular cushion is affixed upon the bench, having a hollow or basin in the centre of it, with a hole from the bottom of the hollow, quite through the cushion, and also through the centre of the bench. This hole receives a strap, which is doubled, and the two ends sewed together. The last is put into the double of the strap, and it is drawn down by a treadle, so as to hold the last firmly in the hollow of the cushion, which is stuffed soft withinside; and as the hole through the cushion is too small for the shoe to pass down, the last can be set in any direction which is most convenient for the sewing; but by relieving the treadle, it can be removed in an instant, turned round, and fixed again to sew another part. A seat can be applied in front of the machine, for the workman to rest himself occasionally: this seat is supported by only two legs, and a piece of wood, which projects horizontally from beneath the seat, and enters into a mortise, made in a part of the frame. Upon this the workman sits astride, as if upon a saddle; and as his work is held before him at a proper height, he sits in an upright posture, which is not attended with the same prejudicial effects as stooping to work upon the knee. The machine is provided with a small tray, or box, behind the cushion, to contain all the small articles which the work requires; also a drawer beneath it for tools, &c.; a whetstone fixed up at a convenient height; and an anvil, which fits into the hollow of the cushion, so as to lie firmly, to hammer the leather upon instead of a lapstone.

Shoe-makers are to make their shoes of sufficient leather, or forfeit 3s. 4d. (1 Jac. I. c. 22.) and journeymen shoe-makers embezling leather shall make satisfaction for damage, or be ordered by justices to be whipped, &c. Persons buying or receiving such leather, are to make reasonable recompence, to be levied by distress, &c. and search is to be made after the same: also leaving their work undertaken, or neglecting it, to be sent to the house of correction for a month. 9 Geo. I. cap. 27. 13 Geo. II. c. 8. See LEATHER.

*SHOE, in the Manege.* A horse-shoe is a piece of flat iron, with two branches or wings, which being commonly forged according to the form of the hoof for which it is designed, is made round at the toe, and open at the heel.

A shoe for all feet, is one that is cut at the toe into two equal parts, which is joined by a rivetted nail, upon which they are moveable in such a manner, that the shoe is enlarged or contracted less or more at pleasure, in order to make it fit all sorts and sizes of feet.

To shoe a horse after the form of a lunette, a patin, &c. see LUNETTE, PATIN, &c. See also SHOING of Horses, &c.

Berenger observes, that the ancients did not shoe their horses, that is to say, they did not nail upon their hoofs any pieces of iron, or of other metal, in the form of the modern horse-shoes: but when they intended to defend them from any thing that might annoy them in travelling, they fastened upon their feet, by means of straps and ligatures, a sort of sandal, flocking, or what we call boots.

These

These were made of sedges twisted together like a mat, or else of leather, and were sometimes strengthened with plates of iron, and adorned by the rich and ostentatious with silver and gold, as in the instances of Nero and Poppæa.

It does not appear in what era, or in what country, the modern art of shoeing took its rise. The earliest proof which the above mentioned writer has met with is the shoe said to have belonged to the horse of Childeric, who lived in the year 481, and is preserved in Montfaucon's Antiquities of France. It perfectly resembles the shoe now in use. Berenger's Horsemanship, vol. i. p. 234.

*SHOES of the Horse and other Animals*, the crooked pieces of iron attached to the hoof of the horse or other beasts, by means of nails. There are various forms and shapes of shoes in common use, and others which are adapted and accommodated to the particular purposes and circumstances of the hoofs. Different sorts of animals, likewise, require different forms in their shoes. In speaking of the shoe which is *concave* on its *lower surface*, it has been remarked by some, that there are certain proportions to be observed in its different parts. Its breadth should be considerably less than the breadth of the common shoe; it is totally unnecessary to cover any part of the sole, especially when care is taken to preserve its natural hardness. The breadth of the shoe at the heels should be one-half of its breadth at the toe. Its thickness should decrease gradually from the toe, so as to be reduced one-half at the extremity of the heels. As to the distribution of the stamp-holes, every person acquainted with the subject knows, that in shoes for the fore-feet, they should be at the toe and quarters, because the wall, or crust, of the fore-feet is stronger at the toe than at the heels. The reverse of this is to be observed in the hind shoes, because the heels and quarters of the hind-feet are commonly stronger than the toe. It is impossible to lay down any general rule for disposing of these holes in bad feet; it must be the business of the farrier to distribute them in such a manner, as to be able to fix the nails in those parts of the crust where the horn is found and firm. Farriers generally multiply these stamp-holes too much, which brings the nails too close together, occasions the horn to break in splinters, and at length destroys the crust.

The following number is recommended for good feet; *viz.* for race-horses six, that is three on each side; for saddle-horses seven, four on the outside and three within, the quarter on this side being weaker than on the other; the same number for coach-horses of the middling size; for large coach-horses four on each side; and for cart-horses, five on the out and four on the inside. It is also of principal importance to determine the *weight of the shoe*, for it is matter of astonishment, to see some horses with shoes weighing each five pounds, making together a burden of twenty pounds of iron attached to their four feet. It is obvious to common sense, that such an additional weight, fixed to the extremity of the leg, must be productive of some inconvenience or other; and, in fact, the muscles are thereby compelled to greater exertion; the ligaments are stretched, and the articulations continually fatigued: and, besides all these evil consequences, the shoe by its weight forces out the nails, and so entirely spoils the texture of the wall or crust, that it becomes often extremely difficult to fix the shoe to the hoof. Why then, it is asked, do not practitioners of the present day, who are daily witnesses of these facts, and indeed are the principal authors of them, apply themselves to the correction of their own errors? The answer, it is feared, is obvious; because he who is uneducated and destitute of sound principles in his art, cannot

turn to real profit the experience he has acquired, nor abandon the path of prejudice and custom, in which he has so long journeyed, but satisfies himself with continuing to imitate and repeat whatever he has seen done by others.

The weights which are proposed, for shoes of different kinds, are nearly as follow:

	lb. oz.
For the strongest sort of cart-horses - - -	2 12
For the smaller horses of this kind - - -	1 12
For the largest coach-horses - - -	1 12
For the smaller ditto - - -	lb. oz. 1 4
For saddle-horses of any height - - -	1 2 to 10
For race-horses - - -	0 4 to 5

And by reducing the superfluous breadths of these shoes, their thickness may, it is supposed, be increased without making any addition to their weight. See *SHOING*.

*SHOES of Cattle*, the small plates of iron that are fastened upon the feet of oxen, or other cattle employed in field or road labour. Shoes of this sort consist, according to some, of a flat piece of iron, with five or six stamp-holes on the outward edge, to receive the nails: at the toe is a projection of some inches, which passing in the cleft of the foot, is bent over the hoof so as to keep the shoe in its proper place. This projection is not, however, employed in the general practice of making these shoes, nor can it in common be of any utility. See *SHOING of Oxen*.

*SHOE of Gold*, in *Commerce*, an ingot used as money in China. Gold is here considered as merchandize; it is sold in regular ingots of a determined weight, which the English call *shoes* of gold; the largest of these weigh 10 taels, and the gold is reckoned 94 touch (that is 94 parts fine in 100), though it is really only 92 or 93. Formerly, 10 taels of silver were given for one tael of gold of the same degree of fineness; but of late, from 100 to 110 taels of silver of 94 touch have been given for 10 taels of gold of 92 or 93 touch; and sometimes from 110 to 120 taels, or even more, of Spanish dollars, reckoned at 92 touch, have been paid for 10 taels of gold. It must be observed, that when gold is exchanged for silver, its price is always valued by the 10-tael weight; and it is sold either above or below touch, as follows: if the gold be 96 touch, and sold at 5 under touch, subtract 5 from 96, and 91 remains; then 91 taels of silver are paid for 10 of gold: if gold be sold at 10 above touch, the fineness being still 96, add 10 to 96; and 106 taels of silver are paid for 10 taels of gold.

We shall here observe that there is but one kind of money made in China, called *cash*, which is not coined but cast, and which is only used for small payments: it is composed of six parts of copper and four parts of lead; it is round, marked on one side, and rather raised at the edges, with a square hole in the middle. These pieces are commonly carried, like beads, on a string or wire. A tael of fine silver should be worth 1000 cash; but on account of their convenience for common use, their price is sometimes so much raised that only 750 cash are given for the tael. See *TAEL*.

*SHOE, Horse*, in *Fortification, Mining, &c.* See *HORSE-SHOE*.

*SHOE, Horse, Head.* See *HORSE-SHOE Head*.

*SHOE of the Anchor*, in *Sea Language*, a small block of wood, convex on the back, and having a small hole sufficient to contain the point of the anchor-fluke on the fore side. It is used to prevent the anchor from tearing or wounding the planks on the ship's bow, when ascending or descending; for which purpose the shoe slides up and down along the bow, between the fluke of the anchor and the plank, as being pressed close to the latter by the weight of the former. *Falconer*.

*SHOE, To, an Anchor.* See *Shoeing the ANCHOR.*

*SHOE-Blocks,* are two single blocks, cut in a solid piece transversely to each other. They are used for legs and falls of the bunt-lines, but are seldom employed.

*SHOE-Houfing.* See *HOUSING.*

*SHOEBURY NESS,* in *Geography,* a cape of England, on the south coast of the county of Essex, at the mouth of the Thames. Here king Alfred erected a fortress against the Danes. There are two villages near North and South Shoebury, both containing together about 200 inhabitants; 5 miles N.E. from the Nore. N. lat.  $51^{\circ} 32'$ . E. long.  $0^{\circ} 45'$ .

*SHOEING of HORSES,* a term applied to the operation of fastening the pieces of iron on the bottom parts of the hoofs, or that of fixing shoes to the feet. These, and some other animals destined to labour, are shod with iron, in order to defend and preserve their hoofs. The shoes of horses should differ according to the feet, as has been already seen. The common form of shoes, and the method of shoeing, are wholly condemned by some, as Mr. Clark, and a new method recommended, which appears founded on just principles, and to have been sanctioned by much experience. It is remarked, that in preparing the foot for the shoe, according to the common method, the frog, the sole, and the bars or binders, are pared so much that the blood frequently appears. The common shoe by its form (being thick on the inside of the rim, and thin upon the outside), must of consequence be made concave or hollow on that side which is placed immediately next the foot, in order to prevent its resting upon the sole. The shoes are generally of an immoderate weight and length, and every means is used to prevent the frog from resting upon the ground, by making the shoe-heels thick, broad, and strong, or raising cramps or caukers on them. From this form of the shoe, and from this method of treating the hoof, the frog is raised to a considerable height above the ground, the heels are deprived of that substance which was provided by nature to keep the crust extended at a proper width, and the foot is fixed as it were in a vice. And by the pressure from the weight of the body, and resistance from the outer edges of the shoe, the heels are forced together, and retain that shape impressed upon them, which it is impossible ever afterwards to remove; hence a contraction of the heels, and of course lameness. But farther, the heels, as has been observed, being forced together, the crust presses upon the processes of the coffin and extremities of the nut-bone: the frog is confined, and raised so far from the ground, that it cannot have that support upon it which it ought to have: the circulation of the blood is impeded, and a wasting of the frog, and frequently of the whole foot, ensues. Hence, it is contended, proceed all those diseases of the feet known by the names of founder, hoof-bound, narrow-heels, thrushes, corns, high soles, &c.

And it has likewise been frequently observed, that there arises from this compression of the internal parts of the foot, a swelling of the legs immediately above the hoof, attended with great pain and inflammation, with a discharge of thin, ichorous, fetid matter: from which symptoms, it is often concluded that the horse is in a bad habit of body (or what is termed a grease falling down), and must therefore undergo a course of medicine, &c. The bad effects of this practice are still more obvious upon the external parts of the hoof. The crust towards the toe, being the only part of the hoof free from compression, enjoys a free circulation of that fluid necessary for its nourishment, and grows broader and longer; from which extraordinary length of toe, the horse stumbles in his going, and cuts his legs. The smaller particles of

find insinuate themselves between the shoe and the heels, which grind them away, and thereby produce lameness. All this is entirely owing to the great spring the heels of the horse must unavoidably have upon the heels of a shoe made in this form. This concave shoe in time wears thin at the toe, and, yielding to the pressure made upon it, is forced wider, and of consequence breaks off that part of the crust on the outside of the nails. Instances of this kind daily occur, in so much that there hardly remains crust sufficient to fix a shoe upon. And further, it is generally thought, that the broader a shoe is, and the more it covers the sole and frog, a horse will travel the better. But, as it has been remarked, the broader a shoe is of this form, it must be made the more concave; and, of consequence, the contracting power upon the heels must be the greater. It is likewise to be observed, that, by using strong broad-rimmed concave shoes in the summer season, when the weather is hot and the roads very dry and hard, if a horse is obliged to go fast, the shoes, by repeated strokes (or friction) against the ground, acquire a great degree of heat, which is communicated to the internal parts of the foot; and, together with the contraction upon the heels, occasioned by the form of the shoe, must certainly cause exquisite pain. This is frequently succeeded by a violent inflammation in the internal parts of the hoof, and is the cause of that disease in the feet so fatal to the very best of our horses, commonly termed a founder. This is also the reason why horses, after a journey or a hard ride, are observed to shift their feet so frequently, and to lie down much. And if we attend further to the convex surface of this shoe, and the convexity of the pavement upon which horses walk, it will then be evident that it is impossible for them to keep their feet from slipping in this form of shoe, especially upon declivities of the streets. It is also a common practice, especially in this place, (Edinburgh,) to turn up the heels of the shoes, into what are called cramps or caukers, by which means the weight of the horse is confined to a very narrow surface, *viz.* the inner round edge of the shoe-rim and the points or caukers of each heel, which soon wear round and blunt; besides, they for the most part are made by far too thick and long. The consequence is, that it throws the horse forward upon the toes, and is apt to make him slip and stumble. To this cause we must likewise ascribe the frequent and sudden lameness horses are subject to in the legs, by twisting the ligaments of the joints, tendons, &c. It is not affirmed that caukers are always hurtful, and ought to be laid aside: on the contrary, it is granted that they, or some such-like contrivance, are extremely necessary, and may be used with advantage upon flat shoes where the ground is slippery; but they should be made thinner and sharper than those commonly used, so as to sink into the ground, otherwise they will rather be hurtful than of any advantage.

It is suggested that the Chinese are said to account a small foot an ornament in their women; and for that purpose, when young, their feet are confined in small shoes. This no doubt produces the desired effect; but must necessarily be very prejudicial to them in walking, and apt to render them entirely lame. This practice, however, very much resembles our manner of shoeing horses; for, if we looked upon it as an advantage to them to have long feet, with narrow low heels, and supposing we observed no inconvenience to attend it, or bad consequence to follow it, we could not possibly use a more effectual means to bring it about than by following the method already described. It is supposed that in shoeing a horse, therefore, we should in this, as in every other case, study to follow nature: and certainly that shoe which is made of such a form as to resemble as nearly as possible

## SHOEING.

possible the natural tread and shape of the foot, must be preferable to any other. But it is extremely difficult to lay down fixed rules with respect to the proper method to be observed in treating the hoofs of different horses: it is equally difficult to lay down any certain rule for determining the precise form to be given to their shoes. This will be obvious to every judicious practitioner, from the various constructions of their feet, from disease, and from other causes that may occur; so that a great deal must depend upon the discretion and judgment of the operator, in proportioning the shoe to the foot, by imitating the natural tread, to prevent the hoof from contracting a bad shape. In order, therefore, to give some general idea of what may be thought most necessary in this matter, it is endeavoured to describe that form of shoe, and method of treating the hoofs of horses, which, from experience, has been found most beneficial. And in this it is to be remembered, that a horse's shoe ought by no means to rest upon the sole, otherwise it will occasion lameness; therefore it must rest entirely upon the crust: and, in order that we may imitate the natural tread of the foot, the shoe must be made flat (if the height of the sole does not forbid it); it must be of an equal thickness all around the outside of the rim; and on that part of it which is to be placed immediately next the foot, a narrow rim or margin is to be formed, not exceeding the breadth of the crust upon which it is to rest, with the nail-holes placed exactly in the middle, and from this narrow rim the shoe is to be made gradually thinner towards its inner edge. And that the breadth of the shoe is to be regulated by the size of the foot, and the work to which the horse is accustomed; but in general, it should be made rather broad at the toe, and narrow towards the extremity of each heel, in order to let the frog rest with freedom upon the ground. The necessity of this has been already shewn. The shoe being thus formed and shaped like the foot, the surface of the crust is to be made smooth, and the shoe fixed on with eight or at most ten nails, the heads of which should be sunk into the holes, so as to be equal with the surface of the shoe. The sole, frog, and bars, as has been already observed, should never be pared, farther than taking off what is ragged from the frog, and any excrescences or inequalities from the sole. Mr. Osmer has remarked, that the shoe should be made so as to stand a little wider at the extremity of each heel, than the foot itself: otherwise, as the foot grows in length, the heel of the shoe in a short time gets within the heel of the horse; which pressure often breaks the crust, and produces a temporary lameness, perhaps a corn. But this method of shoeing horses has been followed long before Mr. Osmer's treatise on that subject was published; and for these several years past it has been endeavoured to introduce it into practice. But so much are farriers, grooms, &c. prejudiced in favour of the common method of shoeing and paring out the feet, that it is with difficulty they can even be prevailed upon to make a proper trial of it. They cannot be satisfied unless the frog be finely shaped, the sole pared, and the bars cut out, in order to make the heels appear wide. This practice gives them a show of wideness for the time; yet that, together with the concave form of the shoe, forwards the contraction of the heels, which, when confirmed, renders the animal lame for life.

It is contended, that in this flat form of shoe, its thickest part is upon the outside of the rim, where it is most exposed to be worn; and being made gradually thinner towards its inner edge, it is therefore much lighter than the common concave shoe; yet it will last equally as long, and with more advantage to the hoof; and as the frog or heel is allowed to rest

upon the ground, the foot enjoys the same points of support as in its natural state. It must therefore, it is supposed, be much easier for the horse in his way of going, and be a means of making him sure-footed. It is likewise evident, that, from this shoe, the hoof cannot acquire any bad form; when, at the same time, it receives every advantage that possibly could be expected from shoeing. In this respect it may very properly be said, that we make the shoe to the foot, and not the foot to the shoe: as is but too much the case in the concave shoes, where the foot very much resembles that of a cat's fixed into a walnut-shell. But it is to be observed, that the hoofs of young horses, before they are shod, for the most part are wide and open at the heels, and that the crust is sufficiently thick and strong to admit of the nail's being fixed very near the extremities of each. But, as has been formerly remarked, from the constant use of concave shoes, the crust of this part of the foot grows thinner and weaker, and when the nails are fixed too far back, especially upon the inside, the horse becomes lame: to avoid this, they are placed more towards the fore part of the hoof. This causes the heels of the horse to have the greater spring upon the heels of the shoe, which is so very detrimental as to occasion lameness; whereas by using this flat form of shoe, all these inconveniences are avoided; and if the hoofs of young horses from the first time that they were shod, were continued to be constantly treated according to the method here recommended, the heels would always retain their natural strength and shape. By following this flat method of shoeing, and manner of treating the hoofs, several horses now under this management, that were formerly tender-footed, and frequently lame, while shod with broad concave shoes, are now quite sound, and their hoofs in as good condition as when the first shoes were put upon them. It is thought that if farriers considered attentively the design of shoeing horses, and would take pains to make themselves acquainted with the anatomical structure of the foot, they would then be convinced, that this method of treating the hoofs, and this form of shoe, is preferable to that which is so generally practised. But it has been alleged, that in this form of shoe, horses do not go so well as in that commonly used. This objection will easily be set aside, by attending to the following particulars. There are but few farriers that can or will endeavour to make this sort of shoe as it ought to be. The iron, in forming it, does not so easily turn into the circular shape necessary, as in the common shoe; and perhaps this is the principal reason why they object to it, especially where they work much by the piece. And as many horses that are commonly shod with concave shoes have their soles considerably higher than the crust, if the shoe is not properly formed, or if it is made too flat, it must unavoidably rest upon the sole, and occasion lameness. Further, that the practice of paring the sole and frog is also so prevalent, and thought to be absolutely necessary, that it is indiscriminately practised, even to excess, on all kinds of feet; and while this method continues to be followed, it cannot be expected that horses can go upon hard ground, on this open shoe, with that freedom they would do if their soles and frogs were allowed to remain in their full natural strength. Experience teaches us, that in very thin-soled shoes, we feel an acute pain from every sharp-pointed stone we happen to tread upon. Horses are sensible of the same thing in their feet, when their soles, &c. are pared too thin. Hence they who are prejudiced against this method, without ever reflecting upon the thin state of the sole, &c. are apt to condemn it, and draw their conclusions more from outward appearances than from any reasoning or knowledge of the structure of the parts. From a due attention likewise to

## SHOEING.

the structure of a horse's foot in a natural state, it will be obvious, that paring away the sole, frog, &c. must be hurtful, and in reality is destroying that substance provided by nature for the defence of the internal parts of the foot: from such practice it must be more liable to accidents from hard bodies, such as sharp stones, nails, glass, &c. From this consideration we shall likewise find, that a narrow piece of iron, adapted to the shape and size of the foot, is the only thing necessary to protect the crust from breaking or wearing away; the sole, &c. requiring no defence if never pared. But there is one observation farther necessary to be made; which is, that the shoe should be made of good iron, well worked, or what smiths call hammer-hardened, that is, beaten all over lightly with a hammer when almost cold. It is well known, that heating of iron till it is red softens it greatly; and when the shoes thus softened are put upon horses' feet, they wear away like lead. But when the shoes are well hammered, the iron becomes more compact, firm, and hard; so that a well-hammered shoe, though made considerably lighter, yet will last as long as one that is made heavier; the advantage of which is obvious, as the horse will move his feet with more activity, and be in less danger of cutting his legs. The common concave shoes are very faulty in this respect; for, in fitting or shaping them to the foot, they require to be frequently heated, in order to make them bend to the unequal surface which the hoof requires from the constant use of these shoes; they thereby become soft, and to attempt to harden them by beating or hammering when they are shaped to the foot would undo the whole. But flat shoes, by making them when heated a little narrower than the foot, will, by means of hammering, become wider, and acquire a degree of elasticity and firmness which it is necessary they should have, but impossible to be given them by any other means whatever; so that any farrier from practice will soon be able to judge, from the quality of the iron, how much a shoe, in fitting it to the circumference of the hoof, will stretch by hammering when it is almost cold: this operation in fitting flat shoes will be the less difficult, especially when it is considered, that as there are no inequalities on the surface of the hoof (or, at least, ought not to be) which require to be bended thereto, shoes of this kind only require to be made smooth and flat; hence they will press equally upon the circumference or crust of the hoof, which is the natural tread of a horse. And a preference has lately been given by Mr. Moorcroft to this kind of shoe, which he calls the "seated shoe," and which he has formed in a die, in the same manner as money is struck in coining. The upper surface of this shoe consists of two parts; an outer part, which is a perfect plane near the rim, corresponding with the breadth of the crust, and called the *seat*; and an inner part, sloping from the seat, and distinguished by the name of the *bevel*. The seat is obviously intended to support the crust in its whole extent, the bevel to lie off the sole; and this part being more or less broad, according to the kind of work proposed to be done, will give the requisite strength to the shoe. As the whole of the crust bears on the seat, it is less liable to be broken than when only a small part of it rests on the shoe. In consequence, likewise, of the crust resting on the flat seat, the weight of the body has a tendency to spread the foot wider in every direction, rather than to contract it, as has been observed to happen with the common shoe, and when afterwards shod with the seated one, it has become wider without the horse having been taken from his usual work; and again, it is observed, that a foot being of a full size and proper form when first shod with the seated shoe, has retained the same size and form without the slightest alteration, as long as the seated shoe was used. By the slope or bevel in the

shoe, a cavity is formed between it and the sole, sufficient to admit a picker, and to prevent pressure on this part, without the sole itself being hollowed, and consequently weakened. For if it be one of the functions of the horny sole to defend the sensible sole, of which, from its situation and nature, no one can doubt, it must be evident that the more perfect it is left, the stronger it must necessarily be, and of course the more competent to perform its office. And though he cannot be sanguine enough to suppose that this shoe will prevent lameness in every case, there is nevertheless sufficient proof from experience to assert, that it will diminish its frequency. Some strong objections have however been made to this form of shoe by Mr. Coleman. If it should be found, where the shoe is applied, that the sole very frequently receives pressure, then we shall demonstrate that the practice is incompatible with the principle. If it be good practice for the sole to receive pressure, then the principle must be erroneous that attempts to make the shoe rest totally on the crust; and if the principle be well founded for the crust only to support the shoe, then, if the sole be in contact with the shoe, the practice must be imperfect. Except a model is taken to every horse's foot, it is impossible for the resting-place of the shoe precisely to fit the crust; for the crust not only varies exceedingly in different horses, but in the same hoof at different parts. The flat surface, therefore, that is only broad enough for the toe, is frequently too broad for the quarters and heels. And in all the shoes he has ever seen of this description, the flat part of the shoe is made of the same breadth at the quarters as at the toe. It is farther to be observed, that this surface very generally exceeds the crust at every part. In the same proportion as the seat of the shoe exceeds the breadth of crust, exactly so much of a flat surface is opposed to an equal quantity of sole. The principle of this shoe is therefore defeated by the practice; for, instead of the seat resting on the crust, it projects over the edge of the sole. It is therefore a fact, that while great pains have been taken to make a flat seat on the shoe, in order to support the crust only, and the web concave, in order to remove pressure from every part of the sole, that the seat has nevertheless very rarely fitted the crust; and consequently the soles of all flat feet, at their connection with the crust, must receive more or less of pressure from the seat of the shoe. Where the sole is concave, this shoe will only rest on the crust; but a shoe that is flat on its whole internal surface would answer the same purpose; for the concave part of the sole opposite to the concavity of the web of the shoe would receive no pressure, even from a shoe wholly flat. He therefore recommends a shoe which has been found free from these and other objections, and which indeed bids fair to supersede the use of every other kind. But before this is noticed, it may be necessary to mention cursorily the shoes proposed by Mr. St. Bel, and Mr. Taplin; but in fact the changes they have introduced are rather novelties than improvements. Mr. St. Bel has indeed committed a great error, that of promoting the arched form of the horse's foot, and thus raising the frog out of the way of pressure, a practice highly injurious to the animal.

It is indeed observed, in respect to Mr. St. Bel's mode of shoeing, by Mr. Coleman, that he employed a shoe with a flat upper surface; but, from not attending to the very important operation of removing the sole under the heels of the shoe, to every kind of hoof, it frequently failed of success. But that the best form of the external surface of the shoe is a *regular concavity*, that is, the common shoe *reversed*. This shoe leaves the hoof of the same figure when shod, as before its application. And it is evident, that a concavity has more points of contact with pavement and other convex

## SHOEING.

convex bodies than a flat or convex surface, and that the horse is consequently more secure on his legs. A shoe that is flat externally, may preserve the hoof equally well in health; but this form is not so well calculated to prevent the horse from slipping as a concavity.

And in explaining the principles and practice of shoeing, it is supposed there are two circumstances necessary to be attended to, *viz.* to cut the hoof and apply the shoe. Before the hoof is protected by iron, some parts require to be removed, and others preserved. This is even of more importance than the form of the shoe. But many have attended chiefly to the shoe, and not to its application or to the hoof; and this error has produced more mischief and more enemies to the Veterinary College, than all the prejudices and calumnies of grooms and farriers. The first thing to be attended to, is to take away a portion of the sole between the whole length of the bars and crust with a drawing knife; for the heels of the sole cannot receive pressure without corns. To avoid this the sole should be made concave, so as not to be in contact with the shoe. If there be any one part of the practice of shoeing more important than the rest, it is this removal of the sole between the bars and crust. When this is done, the horse will always be free from corns, whatever may be the form of the shoe. Besides this, the heels of the shoe should be made to rest on the junction of the bars with the crust; whereas, if the bars are removed, the shoe is supported by the crust only, and not by the solid broad basis of crust and bars united.

And it is added, that it is necessary that the sole should be cut before any other part of the hoof be removed. If the heels have been first lowered by the butteris, then possibly there may not be sufficient sole left to enable a drawing-knife to be applied without reaching the sensible sole; whereas, by cutting the sole in the first instance, we can determine on the propriety of lowering the heels and shortening the toe. The sole can then descend, without the motion being obstructed by the shoe; and any foreign bodies that may have got into this cavity are always forced out when the sole descends, without producing any mischief. When the shoe is applied, the cavity between the sole and shoe should be sufficiently large, at every part, to admit a large horse-picker, and particularly between the bars and crust. If the sole is naturally concave, a shoe with a flat surface applied to the crust, will not touch any part of the sole; and if the sole be flat, or even convex in the middle, or towards the toe, the quarters and heels of the sole will generally admit of being made concave with a drawing-knife, so as not to receive any pressure from a flat shoe. If a shoe with a flat upper surface does not leave ample space for a picker between the sole and shoe, then it is requisite to make either the sole or the shoe concave. When the sole appears in flakes, and thick in substance, it will be better to make the whole of the sole concave by a drawing-knife; and this operation should always be performed before the toe is shortened or the heels lowered. When we have made the sole hollow, then a shoe with a flat surface will rest only on the crust: but if the sole be flat, or convex, and thin towards the toe and middle of the hoof, so as to prevent the possibility of removing the sole at these parts, to form a concavity, then it is necessary to employ a shoe sufficiently concave to avoid pressure, and to admit a picker. In this case, however, the sole at the heels and quarters, even in convex feet, will generally allow of removal with a drawing-knife, and then the quarters and heels of the shoe may be flat. It therefore follows, that where the sole can be made concave, a shoe with a flat surface may with safety be applied; but where parts of the sole, from disease or bad shoeing, become flat, a shoe with a

concave surface is required. As the hoof is always growing, and as the shoe preserves it from friction, the toe of the crust requires to be cut once in about twenty-eight days. The more horn we can remove from this part, the sooner it will be proper to apply a shoe thin at the heels, without mischief to the muscles and tendons, and the horse will be less liable to trip.

And it is stated that the bars and frog should never be removed. What is ragged and detached had better be cut off with a knife by the groom than left to the farrier, who will perhaps remove some of the sound parts. Where the frog is not large and projecting, the heels may be lowered by a rasp, or the butteris, for in every case we are to endeavour to bring the frog in contact with the ground. The frog must have pressure, or be diseased. Nevertheless, when the frog has been diseased for a considerable period, and become soft, it must be accustomed to pressure by degrees. If the quarters are high, and much exceed the convexity of the frog, we should gradually lower the heels, and endeavour to bring the frog and heels of the shoe on the same parallel line. Where work is required of the horse, while the frog is soft and diseased, it may be gradually used to pressure, by lowering the hoof about the tenth of an inch every time of shoeing, until the frog be hard, and equally prominent with the heels; or if the horse is not wanted, great advantage would be derived from his standing without shoes on a hard pavement. But the feet of horses are so variously deformed by bad management, it will be requisite in shoeing to attend to each particular kind of hoof. If any form of shoe be indiscriminately applied for all kinds of feet, it must frequently fail of success: but by proper attention to the different hoofs, we can generally improve the whole foot, so as to employ the shoes recommended at the Veterinary College. And, after the hoof has been properly prepared, then it is requisite to apply a shoe, and to vary its length, breadth, and thickness at the heel, surfaces, &c. according to the hoof. If the heels of the fore-feet are two inches and a half, or more, in depth, the frog sound and prominent, and the ground dry, then only the toe of the hoof requires to be shortened, and afterwards protected by a short shoe made of the usual thickness at the toe, but gradually thinner towards the heel. For a common sized saddle-horse, it may be about three-eighths of an inch thick at the toe, and one-eighth at the heel. The intention is, to bring the frog completely into contact with the ground, to expand the heels, prevent corns, thrushes, and canker. If applied in May or June, when the ground is dry, it may be continued all the summer; and in warm climates, where this is the case, no other protection for the hoof is requisite. And he adds, that so long as the wear of the hoof is not greater than the supply afforded by nature from the coronet, so long may the short shoes be worn; but in wet weather this is not the case: he has known some light horses to wear them the whole year; but such instances are not common. Nevertheless, the short shoe can be employed on most horses with advantage in summer, when the heels are from two and a half to three inches in depth, and the frog equally prominent: but, unless the hoof has been properly preserved, the heels and frog are generally too low for the short shoe. The toe of the horse requires to be shortened as much as possible: but if the frog touches the ground, no part of the heels should be cut; and, by pursuing this practice, the heels will frequently grow sufficiently high to receive the short shoe. After speaking of the application of the short shoe to running horses, it is stated, that during the wet months, we protect the whole crust by a long shoe; and if the heels of the hoof are low, we employ the same shoe in summer. In winter, when the heels are too

## SHOEING.

high, it is better to lower them moderately with a rasp, than to wear them down with a short shoe, as the wet may cause more horn to be destroyed than is necessary to be removed; but it cannot be too often repeated, that the sole between the bars and crust should be taken out before the heels are cut. If the heels are first removed, then possibly the horn left will be insufficient to afford a proper degree of concavity between the bars and crust. Where very high-heeled shoes have been worn, the frog would be liable to injury, as well as the muscles and tendons that bend the leg, from the sudden application of a shoe made thin at the heels. Indeed, whether the shoe or hoof be the cause that elevates the frog, the attention is required to bring it gradually into contact with the ground. We therefore thin the heel of the shoe by degrees, that the frog may become accustomed to hard pressure. The thickness of the last shoe at the heel will always furnish a proper criterion for that to be next applied. If only a small portion of the hoof can be taken from the toe, the heel of the new shoe should be about one-tenth of an inch thinner than the shoe removed; and the growth of the crust will generally be equal to this diminution of iron. By reducing the heels of the shoe in the same proportion as the hoof grows, a thin-heeled shoe may, in a few months, be employed; and yet the horn being preserved at the heel, and cut at the toe, every time of shoeing, the heels (shoe and hoof together) will be as high, and frequently higher, than when the former thick-heeled shoes were employed. The crust that descends at the heels we allow to remain; but subtract an equal quantity of iron from the heels of the shoe, and as much horn as possible from the toe of the hoof. This system should be continued till the heels of the shoe are about one-third the thickness of the toe. In proportion as the crust from the coronet to the toe increases, and the heels decrease in depth, the back sinews and muscles will be put on the stretch. And the converse of this must be equally true, that as the heels are high and the toe short, the muscles and sinews are relieved. It therefore follows, that every atom of horn or iron taken from the toe of the crust, or shoe, tends to relax the parts behind, and that the removal of horn or iron from the heels produces the opposite effect. If these simple facts are kept in view, there can be no difficulty in ascertaining the quantity of iron that may be removed with safety from the heels of any shoe, without danger of mischief to the muscles and tendons.

But in the shoeing of horses that are liable to *cut*, the following useful directions have been given by Mr. Moorcroft. It is contended, that in order to prevent a horse from striking the foot or shoe against the opposite leg, by which it is often bruised or wounded, is an important point; inasmuch as this accident occurs very frequently, and it not only blemishes and disfigures the leg, but also endangers the safety of the rider. The parts struck in the hind-leg, are the inside of the fetlock-joint, and the coronet; in the fore leg, the inside of the fetlock-joint, and immediately under the knee; which latter is called the *speedy cut*, from its happening only when a horse goes fast. Young horses, when first backed, generally cut their fore-legs, although naturally they may be good goers. This arises from their placing the foot on the ground too much under the middle of the breast, in order the better to support the burthen to which they are unaccustomed; but by degrees they acquire the method of balancing the weight, with the foot in the same direction it would naturally have were they without it. It may, therefore, be laid down as a general rule with such horses, that, till they regain their natural method of going, the edge of the inner quarter of the shoe should follow exactly the outline of the crust, but should not be set

within the crust, nor should the crust itself be reduced in thickness; as both these practices tend to weaken the inner quarter, and to deform the hoof. And here it must be observed, that the outer edge of the shoe should, in all cases of found feet, follow exactly the outer edge of the crust, except just at the heel, where it should project a little beyond the line of the hoof. Also, that horses with narrow chests, having their legs placed near together, are apt to cut when they begin to tire; and with these the practice just mentioned should always be employed. Horses that turn their toes much outwards are, of all others, most subject to cut. But in reply to the assertions of some, that this accident also happens to such horses as turn the toes much inwards, he denies having met with a single instance of the kind. In horses of the first description, it has been long observed, that the inner quarters of the hoof were lower than the outer, and that the fetlock-joints were nearer each other than in horses whose feet pointed straight forwards. These two facts probably led to a conclusion, that if the inner quarters were raised to a level with the outer, and so much the more as they were made proportionably higher, that the fetlock-joints would be thrown farther apart, so as to admit of the foot passing by the supporting leg without striking the joint. Accordingly, for the two last centuries, at least, it has been usual to make the inner quarter of the shoe higher than the outer; and not only has this been the general practice, but it has been regularly recommended by almost every writer from that time to the present. And notwithstanding this method has very frequently failed of success, yet repeated disappointment appears never to have led to the circumstance of questioning the truth of the principle. Nay, indeed, the reliance placed upon it has been so strong, probably from the simplicity of the reasoning on which it was founded, that in the cases where it most particularly disappointed expectation, its failure was generally attributed to the practice not being carried sufficiently far; and accordingly the shoe has been still more raised on the inner quarter, and the edges of the crust and shoe have been filed away. When these expedients likewise failed, the last resource has been, a circular piece of leather placed upon the joint to receive the blow of the foot.

It is noticed, that about four years ago, a shoe, with the outer quarter thick and the inner one thin, was applied in a case which had baffled many attempts on the old plan. On the first trial the horse ceased to cut, nor has he ever done it since; which can only be attributed to his having constantly worn the same kind of shoe. And other bad cases, which have occurred occasionally since that period, have been treated in the same way, and with the same success, although for a long time he was at a loss how to explain them. If the action of cutting principally depends on the faulty position of the fetlock-joints, and of the feet with respect to each other, and it seems generally agreed that such is the fact, it should seem that a means which, by raising the outer quarters, must throw the fetlock-joints still nearer to each other, would necessarily increase the defect in question; but as the reverse of this actually takes place, it might induce a suspicion that there exists some other cause of cutting which has been hitherto overlooked. For horses which cut their hind-legs, the shoe, at the outer heel, should be from half an inch to an inch in thickness, according to the kind of horse, and to the degree in which he may cut. The web of the shoe should gradually become thinner till it reaches the toe, which should be of the ordinary thickness, and from which it should slope off, and end like a tip in the middle of the inner quarter. For horses which cut only in a slight degree, a shoe of the same thickness throughout, but reaching on the inner quarter only as far as the middle of the foot, will

## SHOEING.

will in most instances be found sufficient. This shoe, in point of effect, would be equally proper for the fore-feet, were it not that in such horses as are used for the saddle, the fore-feet, being more charged with weight than the hind-feet, are more particularly subject to be injured, and a horse thus shod on the fore-feet might go unsafe: therefore, it is expedient to let the inner quarter of the shoe be thin, and reach to the heel; but the outer edge should be bevelled off, so as to slope inwards. The same kind of shoe is equally well calculated to prevent the speedy cut; observing to bevel off more strongly the part which strikes, and not to put in any nails thereabouts. And here it may be proper to remark, that in found feet, the heel of the shoe should reach as far on the heel of the hoof as to admit of the angle formed by the crust, and the bar resting fully upon it; but it should not be carried quite as far as the end of the heel of the hoof. But in order to ascertain what would happen to a horse shod with different kinds of shoes, the following trials were made.

*Experiment 1.* A horse with a narrow chest, who had never cut, and having parallel shoes on his fore-feet, was trotted at about the rate of eight miles an hour, in a straight line, over ground sufficiently soft to retain slightly the impressions of the shoes, but not to admit the foot to sink into it. Then two parallel lines were drawn along the track, including between them the prints of the shoes. By these it was found, that there was regularly a distance of nine inches and a half between the outer edge of the near fore-shoe and that of the off fore-shoe.

2. Shoes thick in their inner quarter, and like a tip, reaching only half way on the outer quarter, were then used; and it appeared that the distance between the outer edges of the prints of the shoes, taken as before, was regularly reduced to eight inches and a half.

3. The same shoes were afterwards placed on the opposite feet, so that the thick heel was on the outer quarter; and the result, under circumstances exactly the same as in the foregoing experiments, was, that the distance between the outer edges of the prints of the shoes was regularly increased to eleven inches. To account for these results, it is necessary to attend closely to the different effects produced by the weight of the fore part of the body acting upon the two fore-feet, when raised on the inner or outer quarters, during the opposite states of rest and action. And first, with regard to those raised on the inner quarter: whilst a horse so shod is standing still, the fetlock-joints are certainly thrown farther apart than when any other kind of shoe is used. Hence it was concluded, that the limb which supported the body would have its fetlock-joint thrown so much outwards, as to keep it completely out of the way of the foot in motion. But it appears that the impressions made on the ground by such shoes are an inch nearer together, than those made by parallel shoes, and two inches nearer together than those made by shoes raised on the outer quarter. And this may be thus explained: when the horse is at rest, the weight is supported equally by the two fore-feet; but the instant one foot quits the ground, the weight is suddenly transferred to the other; and by the outer quarter being lower than the opposite one, the fore part of the horse has a tendency to fall over to the outside. To prevent this, the moving foot is suddenly brought close to the fetlock of the supporting foot, in order to relieve it by catching the weight; and the foot itself is placed on the ground too much under the middle of the breast. The same circumstance occurs to both feet in their turn: and the horse, being thus in constant danger of falling to one side or to the other, is constrained to bring his feet near together to pre-

serve his balance; and in doing this, strikes the foot against the opposite fetlock. And it frequently happens, that the more the toes are turned outwards, the nearer the fetlock-joints are brought together, and the more the horse is disposed to cut. However, this is true only to a certain extent; for if this faulty position of the lower part of the leg be carried artificially beyond a given point, instead of producing an increased degree of cutting, in most instances it remedies the defect altogether. The reason of this is just the reverse of what takes place when the inner quarter is raised; that is to say, when the weight of the fore part of the body rests only upon one leg, it bears too much upon the inner quarter, from its being lower than the outer quarter; and thus the horse has a tendency to fall over to the inside of the supporting leg. To prevent this, the moving foot is thrown farther from the supporting leg, in order to maintain the balance: and thus the foot misses the fetlock-joint.

In cases where the roads are covered with ice, it becomes necessary to have the heels of horses' shoes turned up, and frequently sharpened, in order to prevent them from slipping and falling; but this cannot be done without the frequent moving of the shoes, which breaks and destroys the crust of the hoof where the nails enter. To prevent this, it has been recommended to those who are willing to be at the expence, to have steel points screwed into the heels or quarters of each shoe, which might be taken out and put in occasionally. And the method of doing this properly, as laid down by Mr. Clark, is first to have the shoes fitted to the shape of the hoof, then to make a small round hole in the extremity of each heel, or in the quarters, about three-eighths of an inch diameter, or more, in proportion to the breadth and size of the shoe: in each of these holes a screw is to be made. The steel points are likewise to have a screw on them, exactly fitted to that in the shoes. Care must be taken that the screw on the points is no longer, when they are screwed into the shoe, than the thickness of the latter. The steel points are to be made sharp: they may either be made square, triangular, or chisel-pointed, as may be most agreeable. The height of the point above the shoe should not exceed a quarter of an inch, for a saddle-horse; they may be made higher for a draught-horse. The key or handle, that is necessary to screw them in and out occasionally, is made in the shape of the capital letter T, and of a sufficient size and strength. At the bottom of the handle a socket or cavity must be made, properly adapted to the shape of the steel point, and so deep as to receive the whole head of the point that is above the shoe. In order to prevent the screw from breaking at the neck, it will be necessary to make it of a gradual taper. The same is likewise to be observed of the female screw that receives it; that is, the hole must be wider on the upper part of the shoe than the under part. The sharp points may be tempered or hardened, in order to prevent them from growing too soon blunt; but when they become blunt, they may be sharpened as at first. These points should be unscrewed, when the horse is put into the stable; as the stones will do them more injury in a few minutes than a day's riding on ice. A draught-horse should have one on the point of each shoe, as that gives him a firmer footing in drawing on ice; but for a saddle-horse, when points are put there, they are apt to make him trip and stumble. And when the shoes are provided with these points, a horse will travel on ice with the greatest security and steadiness, much more so than on causeway or turnpike roads, as the weight of the horse presses them into the ice at every step. And in addition to the common shoe for horses that have found feet, there are also

others of various shapes, determined by the necessity of the case, as by the different derangements and diseases to which the horse's foot is liable. See SHOE.

**SHOEING of the Ass and Mule.** With respect to what concerns the shoeing of other animals, Mr. Clark thinks that the mule, being an animal uncommon in this country, the ass of no great value, and the ox not generally employed in labour, it is needless to say much on the subject. The shoe for the fore-feet of the mule is very similar to that which the farriers call the *bar-shoe*. It is very wide and large, especially at the toe, where it sometimes projects four inches and upwards beyond the hoof. This excess is given it with a view to enlarge the basis of the foot, which is in general exceedingly narrow in this animal. The shoe for the hind-feet is open at the heels, like the horse's shoe; but it is lengthened at the toe, like the preceding one. And it is added, that the foot of the ass, having the same shape as that of the mule, requires the same kind of shoe, with this only difference, that the shoe of the fore-foot is not closed at the heels, and that its edges do not project so much beyond the hoof. The same form of shoe is used for the hind-feet of this animal.

**SHOEING of Oxen,** the business of fixing shoes upon animals of this kind, and which is constantly necessary wherever they do any sort of field or road labour; but it is a practice which is yet far from being performed in a perfect manner. Mr. Clark remarks, that in many parts of France, where the ox is used for draught, it is sometimes necessary to employ eight shoes, one under each nail; or four, one under each external nail; and sometimes only two, one under the external nail of each fore-foot. In this country two pieces, or shoes, to each foot are generally, however, made use of; being mostly fixed on, especially in the northern districts, with three or four large-headed nails to each shoe. They are fitted on in a similar manner to those of the horse. But from the shoes of these animals being, from the smallness of the pieces, so liable to break, it has been suggested to have them shod with whole shoes, in the manner of the horse; but how far this is a practice that will answer, must depend upon future trials. It is probable, that in this way the foot will be too much confined to succeed in any very perfect manner. Where oxen are left without shoeing, they are continually liable to become lame, and to be incapable of going on with their work. As there is much trouble in the shoeing these animals, from its being necessary to cast them each time, it has been found requisite to have recourse to contrivances for shoeing them standing. See OX-SHOEING Machine.

**SHOEMAKERS' CHIPS,** in *Agriculture*, the refuse cuttings pared off in making shoes, which, when collected in sufficient quantity, are found useful as a manure. See MANURE.

**SHOENECH,** in *Geography*, a Moravian settlement in Pennsylvania, near Nazareth, begun in 1757.

**SHOESHARMO,** a town of Little Bucharja; 60 miles S.W. of Acha.

**SHOGLE.** See CHOU.

**SHOKET,** a town of Syria, in the pachalic of Damascus, on the Orontes; 22 miles S. of Antakia.

**SHOLAVENDEN,** a town of Hindooistan, in Madura; 14 miles W.N.W. of Madura.

**SHOLAVARAM,** a town of Hindooistan, in the Madwar; 14 miles S. of Tripatore.

**SHOLINGUR,** a town of Hindooistan, in the Carnatic; 20 miles S. of Bomrauzepollam.

**SHOOCAMPETTY,** a town of Hindooistan, in Coimbatore; 5 miles S.S.W. of Caroor.

**SHOODS,** in *Rural Economy*, a provincial term applied to hulls.

**SHOOLARUMBOO,** in *Geography*, a town of Hindooistan, in the province of Dindigul; 17 miles N.N.W. of Dindigul.

**SHOOLERAMCOTTA,** a town of Hindooistan, in the province of Dindigul; 7 miles N. of Dindigul.

**SHOOMTSHA,** one of the Kurile islands, the nearest to Kamtschatka. The channel between the Lopatka and this island is 15 versts broad. The length of the island from N.E. to S.W. is 50, and the breadth 30 versts. The land is low, with moderate ridges of hills. The eastern coasts, about the middle of the island, form steep shores and rocky shelves, and are for some way into the sea studded with rocks. Here is one, and it is said that a vein of silver has been formerly worked. In the centre of the island is a lake, five versts in circuit, which flows by a streamlet into the sea. In this are caught fine salmon, and several other kinds of fish. There are no standard trees upon the island, but merely bushes of alder, willow, and an espalier kind of pine, or Siberian cedar, on which grow little cedar-nuts. The inhabitants are not genuine Kuriles, but of Kamtschadale descent; of these 46 persons pay tribute. N. lat. 51° 25' to 52°. E. long. 156° 14'.

**SHOOR,** a town of Hindooistan, in Lahore; 15 miles S.E. of Koothaub.

**SHOOT,** in *Agriculture*, the young branch of any sort of plant, which is afforded in one season. It also signifies a young animal of the cattle kind, in some districts.

**SHOOT,** in the *Sea Language*. They say the ballast shoots, when it runs over from one side to another.

**SHOOTE,** among neat cattle, an affection of the bowel kind, with which calves are often attacked a few days after calving. The usual symptoms are, first, a colic or pain that is more or less violent, and is frequently very severe and dangerous, especially when it is contagious. This colic is terminated, and the calf relieved, by a discharge taking place from the bowels; though this sometimes proves fatal before the shoote appears. Secondly, a loathing and refusing of food, even previous to the discharge; which decreases and increases according to the duration and violence of the disorder. Where the disease prevails, the best medicine which can be administered is that of eggs and flour properly blended with oil, melted butter, and aniseed, linseed, or similar mucilaginous vegetable matters; and milk simply mulled with eggs may be often given with much advantage.

**SHOOTER'S HILL,** in *Geography*, a hill in the county of Kent, between London and Dartford.

**SHOOTING.** See GUNNERY and PROJECTILE.

**SHOOTING of Bombs.** See BOMB.

**SHOOTING with Air.** See WIND-GUN.

**SHOOTING, Malicious,** in *Law*. See MAHIM.

**SHOOTING of Salts.** It is to be observed, that the figures arising from the shooting of dissolved salts are not constantly the same, but vary according to different circumstances, such as when they happen to shoot more or less hastily, or in different proportions of liquor. See SALT.

**SHOOTING Point,** in *Geography*, a cape of Scotland, on the south coast of the county of Fife, and east side of Largo bay.

**SHOOTS, HOT.** See HOT.

**SHOOT, Water.** See WATER.

**SHOP-LIFTER,** a person who, on pretence of buying goods or otherwise, takes an opportunity to steal them; and if the goods amount to the value of five shillings, though

though no person be in the shop, he is guilty of felony without benefit of clergy, by 10 & 11 W. III. c. 22.

SHORAB, in *Geography*, a town of Persia, in the province of Segestan; 30 miles W. of Meimend.

SHORAY, a town of Hindoostan, in the circar of Chanderee; 22 miles N. of Kimlaffa.

SHORE, JANE, in *Biography*, the concubine of king Edward IV., was the wife of Mr. Matthew Shore, a goldsmith in Lombard-street, London. Historians represent her as extremely beautiful, cheerful, and generous. The king, it is said, was no less captivated with her temper than her person; she never made use of her influence over him to the prejudice of any one; her importunities were always in favour of the unfortunate. After the death of Edward, she attached herself to the lord Hastings; and when Richard III. cut off that nobleman as an obstacle to his ambitious schemes, Jane Shore was arrested as an accomplice, on the accusation of witchcraft. For this she was doomed to a public penance, and to the loss of her property. She was alive, but probably in a very wretched state, under the reign of Henry VIII. when she was seen by sir Thomas More, poor and old, and without the smallest trace of her former beauty. Mr. Rowe, in his tragedy of Jane Shore, has adopted the popular story, related in the ballad, of her perishing with hunger in a place where Shoreditch now stands. But Stow allures us, that this place had its name long before her time.

SHORE, JOHN, a famous performer on the trumpet. Matthias Shore, the father of John, and Colley Cibber's wife, was sergeant-trumpet, in which office he was succeeded, first by his brother William Shore, and afterwards by his son John. His daughter, Mrs. Cibber, had been a scholar of Purcell in singing and playing on the harpsichord; in the exercise of which talents at home, her conquest over the heart of Colley Cibber first began. Purcell, from his connexion with the family, and his admiration of John's performance on the trumpet, took every opportunity in his power to employ him in the accompaniment of his songs and other theatric compositions; and this accounts for the frequent use he made of that martial and field instrument, even when the subject of the poetry was pacific. John Shore lived till the year 1753, when he was succeeded as sergeant-trumpet, by that admirable performer the late Mr. Valentine Snow, whose exquisite tone and fine shake must be still remembered by many persons living, who have heard him at Vauxhall, and in Mr. Handel's oratorios.

SHORE, among *Builders*, &c. See SHOAR.

SHORE, or *Common Shore*, a corruption of *sewer*. See SEWERS.

SHORE, in *Agriculture*, a sort of artificial drain or course formed in low flat lands for the purpose of freeing and relieving them from the collected surface-waters. The want of shores is now most common in waste and unreclaimed lands; but it occasionally occurs in those of other kinds, in wet seasons, to the great injury and prejudice of the prevailing crops, and the future productiveness of the land, as the loitering surface-water can get off in no other way. There are very great extents of even appropriated lands, in some cases, that are greatly damaged and inconvenienced by water lodging and stagnating in the furrows of the ridges and the ditches, for want of having sufficient proper shores, or public drains, for drawing it off; and of public proper laws and regulations for enforcing the re-opening and the cleansing, from time to time, of those which have been formed at former periods; as well as for the preserving of the whole always in a suitably open state.

It is extremely probable, that a large proportion of the

low flat lands of this country, which are now in a somewhat dry condition, were, in their natural state, liable to be at times covered with water. This appears to have been the case, from the compact gluey composition of the soil, and the slight covering of black vegetable earth which still forms the surface of them, where the work of tillage has not been performed upon them. And, from many of such low flat grass lands now lying in a tolerably dry state, from large tracts of those of the arable kind, whose soils are now barely out of the reach of water, which, in wet seasons, fill their drains and ditches to the brim, as well as from the less admissible evidence of tradition in low-lying districts,—it would seem, it is said, to be equally probable, that much industry and exertion have at former periods been employed, to free the lands of this sort in the country from the state in which nature and time had placed them.

The feudal system is supposed to have been particularly favourable to undertakings of this useful kind, and that since its decline, the courts of the manorial description, which succeeded and survived it, have contributed to enforce its beneficial regulations. But that as they have now for the most part lost their power, existence, and authority, or where they are still continued and retain them, what relates to the business of public drains and water-courses, in their management, is too often neglected and overlooked. Hence it is noticed by a late writer, that, "relative to this important department of rural economics and internal policy, the country may be said to have been moving, and, in a general view of it, still continues to move, in a retrograde direction."

In a great number of situations, vast injury and inconvenience are at present sustained from the want of the shores, drains, ditches, and other outlets for drawing off the water being kept properly open and sunk for its discharge into the adjoining rivers, brooks, or seas.

Some sufficient power and authority for the regulation of all matters of this nature should certainly exist in every district of the kingdom; which is not now the case, at least to any full and effectual extent, as many most important benefits and advantages would necessarily result from it, in the management and improvement of lands, as well as in the increase of the produce of it.

It has been suggested, that a great deal may be effected in this way, by the having recourse to the appointment of *juris* for the conducting of the business of *shores* and *water-courses*, wherever there are the slightest remains of the existence of manorial courts. And that, even where there is nothing of this sort to be met with, it would not fail to have a good effect, in many cases, where the lands are considerable, to have *standing inquests*, chosen from among the neighbouring tenantry in an annual or other manner, for the purpose of directing the proper regulation of the public *shores*, *drains*, *water-courses*, and other modes of conveying away the superabundant water from the land.

SHORE, *Sea*, is a general name for the sea-coast of any country. A bold shore is a coast which is steep and abrupt, so as to admit the closest approach of shipping without exposing them to the danger of being stranded.

The shores of the sea are divided, by count Marigli, into three portions, according to which, all his descriptions, in his account of the basin of the sea, are given. The first part of the shore is that tract of land to which the sea just reaches in storms and high tides, but which it never covers; the second part of the shore is that which is covered in high tides and storms, but is dry at other times; and the third is the descent from this, which is always covered with water.

The *first* part is only a continuation of the continent, and suffers no alteration from the neighbourhood of the sea, except that it is rendered fit for the growth of some plants, and wholly unfit for that of others, by the saline steams and impregnations; and it is scarcely to be conceived by any but those who have observed it, how far inland the effects of the sea reach, so as to make the earth proper for plants, which will not grow without this influence, there being several plants frequently found on high hills and dry places, at three, four, and more miles from the sea, which yet would not grow, unless in the neighbourhood of it, nor will ever be found elsewhere.

The *second* part or portion of the shores is much more affected by the sea than the former, being frequently washed and beaten by it. Its productions are rendered salt by the water, and it is covered with sand, or with the fragments of shells in form of sand, and in some places with a tartareous matter deposited from the water, and the colour of this whole extent of ground is usually dusky and dull, especially where there are rocks and stones, and these are covered with a slimy matter.

The *third* part of the shores is more affected by the sea than either of the others, and is covered with an uniform crust of the true nature of the bottom of the sea, except that plants and animals have their residence in it, and the decayed parts of these alter it a little.

SHORE of *Muchul*, in *Geography*, a cape of Scotland, on the E. coast of the county of Kincardine, so called from a village near the coast; 3 miles N. of Stonehaven.

SHOREDITCH, ST. LEONARD, a parish in the hundred of Ossullton, and county of Middlesex, England, is situated in the northern suburbs of London, and forms one of the twenty-three out-parishes of Middlesex and Surrey, which are mentioned in the bills of mortality. This parish is of great extent, and is divided into four liberties, called the liberties of Churchend, Hoxton, Holywell, and Moorfields. The church, a modern edifice, was opened for divine service in August, 1740, having been erected in place of a very old church, which Ellis, author of the "History and Antiquities of Shoreditch," states to have been of Saxon origin. The ascent to the church is by a double flight of steps leading under a portico, supported by four Doric columns. The body is plain in its architecture, but is well lighted by spacious windows. The steeple, which rises to a very considerable height, has rather a handsome appearance. In the old church were a variety of monuments and brasses in memory of persons of distinguished rank; among whom were the countess of Westmorland (daughter to Edward, duke of Buckingham), who died in 1553; Eleanor, countess of Rutland, who died in 1551; and two sons of the said countess of Rutland; but none of those in the new church possess any interest. This parish abounds with alms-houses, established either by public city companies or by private individuals. In Holywell was anciently a priory for nuns of the Benedictine order, which was founded early in the twelfth century, and possessed a revenue of 293*l.* *per annum* at the time of the dissolution. According to the parliamentary returns of 1811, this parish contained 7658 houses and 43,930 inhabitants. The History and Antiquities of the Parish of St. Leonard Shoreditch, by Henry Ellis, quarto, 1797.

SHOREHAM, New, a borough and market-town in the half hundred of Fishergate, rape of Bramber, and county of Sussex, England, is situated upon the coast of the English Channel, at the distance of about 6 miles W.

from Brighthelmston, and 55 miles S. by W. from London. This town is indebted for its origin to the decay of Old Shoreham, which is now a very trifling village, but appears to have been a place of considerable importance in ancient times. New Shoreham is a borough by prescription, and has sent members to parliament since the year 1295, the 23d year of the reign of Edward I. In 1771 it became conspicuous in the annals of electioneering, by the development of a remarkable scene of corruption practised in the election of members for the parliament then assembled. The returning officer having returned a candidate with only 37 votes, in prejudice to another who had 87, of which he had rejected 76, without assigning any satisfactory reason for so doing, was called upon to account for his conduct at the bar of the house of commons; when he defended himself, by stating that those whom he had queried formed part of a society, called the Christian club, the ostensible object of which was only a mask to cover its real one, the setting the borough to sale to the highest bidder. In consequence of these assertions, the house resolved itself into a committee to inquire into the truth; and being fully satisfied on that head, after a patient investigation, it was resolved to incapacitate the members of the club from voting at elections in future. An act was accordingly passed soon afterwards, by which 69 persons were disfranchised, and the right of voting was declared to belong to every freeholder, above 21 years of age, "who shall have, within the rape of Bramber, a freehold of the clear yearly value of forty shillings; and in such persons as by the usage of the borough have, or shall hereafter have, a right to vote at such elections." By this extension of the elective franchise, the number of voters has increased from about 200 to 1200 persons.

The church of New Shoreham is a curious and interesting specimen of ancient Norman architecture. At present only the east end is fitted up and appropriated to divine service, as the nave, or part westward of the tower, has been entirely destroyed. It consisted of a nave, transept, tower, and choir; and by its style of architecture, appears to have been built near the end of the twelfth century. See a beautiful engraving of it in Cooke's "Southern Coast of England."

New Shoreham is governed by two constables, annually elected, who are the returning officers. The market-day is Saturday, weekly; and there is a fair on the 25th of July. It was formerly a town of more relative note than at present, and had a priory of Carmelite or White Friars, founded by sir John Mowbray, knight; as also an hospital dedicated to St. James. It is chiefly remarkable, however, for being built upon the spot where Ella, the Saxon, landed, with supplies from Germany in aid of his countrymen, Hengist and Horsa. According to the parliamentary returns of 1811, the parish contains 168 houses, and 770 inhabitants. History of the Boroughs of Great Britain, and the Cinque Ports, 3 vols. 8vo. 1792. Beauties of England and Wales, vol. xiv. by F. Shoberl, 1813.

SHOREHAM, a township of America, in the state of Vermont, and county of Addison, on the E. side of lake Champlain; containing 2033 inhabitants.

SHOREHAVEN, a sea-port on the south coast of the island of Stromloe, with a good harbour, called Tros. N. lat. 61° 40'. E. long. 11° 7'.

SHORL, in *Mineralogy*. See SCHORL.

SHORLING and MORLING, in our *Old Writers*, words used to distinguish fells of sheep; *shorling* being the fells after the fleeces are shorn off the sheep's back; and *morling* the fells shorn off after they die or are killed. In some parts of England they understand by a *shorling*, a sheep whose

whose fleece is shorn off; and by a *morling*, a sheep that dies.

**SHORN VELVET.** See **VELVET.**

**SHORT, THOMAS**, in *Biography*, a physician of the early part of the last century, and the author of many works relating to chemistry, meteorology, and medicine. Few particulars are recorded of his life, which seems to have been spent more in the pursuit of science, than in the exercise of his profession. He was a member of the Royal Society. The following are the principal works which he left. "Memoir on the Natural History of Medicinal Waters," 1725. "A Dissertation on Tea," 1730. "Natural History of the Mineral Waters of Yorkshire, Lincolnshire, and Derbyshire," 1733. "A General Chronological History of the Air, Weather, Seasons, Meteors, &c. for the Space of 250 Years," 1740. "Discourses on Tea, Sugar, Milk, made Wines, Spirits, Punch, Tobacco, &c." 1749. "New Observations, Natural, Moral, Civil, Political, and Medical, on Bills of Mortality," 1750. See **ELOY**, **DICT. HIST.** and the Works of **Short**.

**SHORT, JAMES**, an eminent optician, was born at Edinburgh in the year 1710. At the age of ten he lost his parents, and being left in a state of indigence, he was admitted into Heriot's Hospital, where he soon shewed a fine mechanical genius, by constructing for himself a number of curious articles with common knives, or such other instruments as he could procure. At the age of twelve he was removed from the hospital to the High-school, where he shewed a considerable taste for classical learning, and he soon became at the head of his forms. He was intended for the church, but after attending a course of theological lectures, he gave up all thoughts of a profession, which he found little suited to his talents, and from this period he devoted his whole time to mathematical and mechanical pursuits. He was pupil to the celebrated Maclaurin, who perceiving the bent of his genius, encouraged him to prosecute those particular studies for which he seemed best qualified by nature. Under the eye of his preceptor he began, in 1732, to construct Gregorian telescopes; and, as the professor observed, by attending to the figure of his specula, he was enabled to give them larger apertures, and to carry them to greater perfection, than had ever been done before him.

In 1736 Mr. Short was invited to London by queen Caroline, to instruct William, duke of Cumberland, in the mathematics; and on his appointment to this office, he was elected a member of the Royal Society, and patronized by the earls of Macclesfield and Morton. In the year 1739 he accompanied the former to the Orkney islands, where he was employed in making a survey of that part of Scotland. On his return to London he established himself as an optician, and in 1743, he was commissioned by lord Thomas Spencer to make a reflector of twelve-feet focus, for which he received 600 guineas. He afterwards made several other telescopes of the same focal distance, with improvements and higher magnifiers: and in 1752 he completed one for the king of Spain, for which, with the whole apparatus, he received 1200*l.* This was the noblest instrument of the kind that had ever been constructed, and has probably not been surpassed, unless by the grand telescopes manufactured by Dr. Herschel.

Mr. Short was accustomed to visit the place of his nativity once every two or three years during his residence in London, and in the year 1766 he paid his last visit to Scotland. He died in June 1768, after a very short illness, when he was in the 58th year of his age. His eminence as an artist is universally admitted, and he is spoken of by

those who knew him from his youth upwards, as a man of virtue and very amiable manners.

**SHORT Accent**, in *Grammar*. See **ACCENT.**

**SHORT Crooks**, in *Agriculture*, are a sort of crooks, which are formed of bent pieces of wood of the oak or elm kind, and so contrived as to be fixed on the horse's back, the ends or crooks turning up, so as to secure the loads on them. They are in use in the counties of Devon and Cornwall, in the latter of which they have both short and long crooks, as they term them, which are made use of for carrying sheaf-corn, hay, faggot, billet-wood, slate, and flag-stones. They are a relic of the old mode of carrying loads in hilly districts. Single-horse carts would probably answer the purpose in a far better way. See **CART.**

**SHORT Grass**, in *Gardening*, a term applied to the pieces of grass which are kept in a continually mown, short, close state, as on lawns, and in pleasure-grounds, or other situations about country residences. The portions of mown or short grass about seats and houses of the above sort in the modern improved modes of laying out pleasure-grounds, are mostly much more confined in their limits than was formerly the case; as they are not only troublesome, but very expensive in keeping in that proper order and neatness which is necessary for the purpose of ornamental effect, and the utility of walking upon them as occasion may require; and because a much better and more natural effect is found capable of being produced without them; while at the same time the lands can be rendered useful in supporting animals, and of course no loss be sustained.

Where pieces of short grass are, however, formed, and to be kept in order, it will be necessary to roll, mow, and sweep up the grassy litter in a clean neat manner from them once or oftener in the course of the week during the spring season, and frequently at other times. The refuse litter, thus procured, may be employed for different garden purposes, where it cannot be converted to better uses. See **LAWN** and **PLEASURE-Ground.**

It is mostly in too dirty a state to be applied as food for any sort of cattle flock.

**SHORT-Grass Scythe**, that sort of tool of this kind which is employed in mowing short grass. Scythes for this use should be rather short, and laid in the shaft with the edges low, in order that the grass may be cut in a close neat manner, without leaving any scythe ridges or bulks, as they are usually termed. The swathes or scythe casts, in performing this sort of mowing, are commonly made narrow, in the intention, that the grass may be well and levelly cut out of the bulks or parts under the swathes, and by such means have a more neat and even appearance. See **SCYTHE.**

**SHORT Smalls**, in *Agriculture*, a sort of oat, which is so named on account of its remarkable shortness. It is much grown in the county of Essex, and is a thick, full, weighty sort, that succeeds well on moist lands of the more dry kind. See **OATS.**

**SHORT Sails**, in a *Man of War*, are the same with *fighting sails*, being the fore-sail, main-sail, and fore-top-sail, which are all that are used in fight, lest the rest should be fired and spoiled: besides the trouble of managing them when a ship gives chase to another.

If a chase shews a disposition to fight, they say the chase *strips into her short sails*, i. e. puts out her colours in the poop, her flag at the main-top, and her streamers or pendants at the yard's arms; furls her sprit-sail, pecks her mizen, and flings her main-yard.

*To shorten Sail.* See **SAIL.**

**SHORTFORD**, *q. d. fore-clofe*, an ancient custom in the city of Exeter, when the lord of the fee cannot be answered rent due to him out of his tenement, and no distress can be levied for the same. The lord is then to come to the tenement, and there take a stone, or some other dead thing, off the tenement, and bring it before the mayor and bailiff, and thus he must do seven quarter-days successively, and if on the seventh quarter-day the lord is not satisfied his rent and arrears, then the tenement shall be adjudged to the lord to hold the same a year and a day; and forthwith proclamation is to be made in the court, that if any man claims any title to the said tenement, he must appear within the year and day next following, and satisfy the lord of the said rent and arrears: but if no appearance be made, and the rent not paid, the lord comes again to the court, and prays that, according to the custom, the said tenement be adjudged to him in his demesne as of fee, which is done accordingly, so that the lord hath from thenceforth the said tenement, with the appurtenances, to him and his heirs.

**SHORT-JOINTED**, in the *Manege*. A horse is said to be short-jointed, that has a short pattern; when this joint, or the pattern, is too short, the horse is subject to have his fore-legs from the knee to the coronet all in a straight line. Commonly short-jointed horses do not manege so well as the long-jointed; but out of the manege, the short-jointed are the best for labour or fatigue, especially those of the farm breed.

**SHORT-SIGHTEDNESS**, *MYOPIA*, a defect in the conformation of the eye, wherein the crystalline, &c. being too convex, the rays reflected from different objects are refracted too much, and made to converge too fast, so as to unite before they reach the retina, by which means vision is rendered dim and confused. See *MYOPS*.

A learned author thinks it probable, that out of so great a number of short-sighted persons as are daily to be met with, few are born so, for it generally grows upon young people at the age of twenty or twenty-five, and therefore might possibly be prevented by using their eyes, while young, to all sorts of conformations, that is, by often looking through glasses of all sorts of figures, and by reading, writing, or working with spectacles of several degrees of convexity; for whatever be the powers by which the eye conforms itself to distinct vision, they may possibly grow weak, or lose their extent one way or other, for want of variety of exercise. It seems an opinion without foundation, to think that such an exercise of the eyes can anywise injure them, provided due care be taken to avoid looking at objects that are too bright.

Short-sightedness may come by accident; of this we have a remarkable instance, mentioned by Dr. Briggs in his *Ophthalmographia*, of a person upwards of seventy years old, who had used spectacles for ten years, and yet by catching cold, he suddenly became so short-sighted, that he could not distinguish objects three feet off, and after the cold and defluxion were cured, he continued to read the smallest print without spectacles for many years.

Dr. Smith mentions a young gentleman, who became short-sighted immediately after coming out of a cold bath, in which he did not totally immerse himself, and has ever since used a concave glass for many years.

It is commonly thought that short-sightedness wears off in old age, on account of the eye becoming flatter: but the learned doctor questions whether this be matter of fact, or hypothesis only.

It is remarkable, that short-sighted persons commonly write a small hand, and love a small print, because they can see more of it at a view. That it is customary with them

not to look at the person they converse with, because they cannot well see the motion of his eyes and features, and are therefore attentive to his words only. That they see more distinctly, and somewhat farther off, by a strong light than by a weak one; because a strong light causes a contraction of the pupil, and consequently of the pencils, both here and at the retina, which lessens their mixture, and consequently the apparent confusion; and, therefore, to see more distinctly, they almost close their eye-lids, for which reason they were anciently called *myopes*. Smith's Optics, vol. ii. Rem. p. 10. &c.

Dr. Jurin observes, that persons who are much and long accustomed to view objects at small distances, as students in general, watch-makers, gravers, painters in miniature, &c. see better at small distances, and not so well at great distances, as the rest of mankind. The reason is, that in the eye, as well as in other parts, the muscles, by constant exercise, are enabled to contract themselves with more strength, and by dilate are brought to less strength. Hence, in the persons before-mentioned, the greater muscular ring of the uvea contracts more easily and strongly, and the cornea more readily obeys the contraction of the ring, whence they see better at small distances. And the cornea, by being thus often and long bent into a greater convexity, does by degrees lose something of its elasticity, so as not to return to its natural elasticity, when the muscular ring ceases to act upon it. This is one cause of their not seeing so well at great distances: also the ligamentum ciliare, being seldom employed to lessen the convexity of the capsula, does by degrees become less capable of performing that office: and the capsula being seldom drawn out, and put into tension, must lose something of its distensible quality, so as less easily to comply with the action of the ligament. And this is another cause of their not seeing so well at great distances. Jurin, Essay on dist. and indist. Vision.

The ordinary remedy for short-sightedness is a concave lens, held before the eye, which making the rays diverge, or at least diminishing much of their convergency, makes amends for the too great convexity of the crystalline.

Dr. Hook suggests another remedy. Finding that many short-sighted persons are but little helped by concaves, he recommends a convex glass, placed between the object and the eye, by means of which the object may be made to appear at any distance from the eye: and consequently, all objects may be thereby made to appear at any distance from the eye, so that the short-sighted eye shall contemplate the picture of the object in the same manner as if the object itself were in the place. It is true, the image will appear inverted, but we have expedients to remedy this too; for, in reading, there needs nothing but to hold the book upside down. To write, the best way, in this case, will be, for the person to learn to do it upside down. For distant objects, the doctor asserts, from his own experience, that with a little practice in contemplating inverted objects, one gets as good an idea of them as if seen in their natural posture.

**SHOSTACK**, in *Commerce*, a money of account in Poland and Hungary. In Hungary, a shostack is 2 imperial groschen, or 6 creutzers; an imperial grosche, or kayser grosche, is 2 polturats, 3 creutzers, or 12 pfenings; a polturat is 6 pfenings, and a creutzer 4 pfenings. A Hungarian grosche is worth 2 creutzers in Upper Hungary, but 2½ creutzers in Lower Hungary: thus, 5 groschen in Upper Hungary, or 6 groschen in Lower Hungary, = 1 kayser grosche. A rixdollar of account is worth 1½ imperial florin, 1½ Hungarian florin, 15 shostacks, 30 imperial groschen, or 90 creutzers. An imperial florin is 10 shostacks, or 20 imperial groschen, and a Hungarian florin, 8½ shof-

8½ shostacks, or 17½ imperial groschen; thus, 7 florins of the empire = 8 Hungarian florins.

In Poland, the florin of 30 groschen or grosz, each of which is divided into 18 pfenings, contains 2½ shostacks, 90 shillings, or 270 pfenings. A shostack is worth 12 groschen, or 36 schillings; a grosche, 2 schillings; a schilling, 3 pfenings. Kelly's Cambist.

SHOT, INDIAN, in *Botany*. See CANNA.

SHOT, in the *Military Art*, includes all sorts of ball or bullets for fire-arms, from the cannon to the pistol. See BULLET, CANNON, &c.

Those for cannon are of iron; those for muskets and pistols are of lead.

SHOT, for ordnance, especially in the sea service, are of several sorts: as,

SHOT, *Round*, balls or globes of iron fitted to the bore of the piece.

SHOT, *Bar*, is formed of two bullets, or rather half bullets, joined together by an iron bar, serving to cut down masts, sails, &c.

SHOT, *Cafe, Chain, Grape, Langrel, Random, Star*, and *Trundle*, see the respective articles. See also FIRE-ARMS.

SHOT, for fowling, is otherwise called *hail*, by reason of its figure and size.

The method of casting it is as follows: the lead being melted, stirred, and skimmed, a quantity of powdered yellow orpiment is strewed in it, as much as will lie on a shilling, to twelve or fifteen pounds of lead; the whole being well stirred, the orpiment will flame.

To judge whether there be orpiment enough in, a little of the lead is dropped into a glass of water, and if the drops prove round, and without tails, there is orpiment enough, and the degree of heat is as it should be.

This done, a copper plate, hollow in the middle, and three inches in diameter, bored through with thirty or forty small holes, according to the size of the shot, is placed on an iron frame, over a tub of water, four inches above the water; the hollow part is to be very thin; on this plate are laid burning coals, to keep the melted lead in fusion. The lead is now poured gently, with a ladle, on the middle of the plate, and it will make its way through the holes in the bottom of the plate into the water in round drops.

Great care is taken to keep the lead on the plate in its proper degree of heat: if too cold, it will stop the holes; and if too hot, the drops will crack and fly.

The shot, thus made, are dried over a gentle fire, always stirring them that they do not melt; this done, the greater are separated from the smaller by passing them through sieves for that purpose.

SHOT, *Fresh*. See FRESH Shot.

SHOT, *Hip*. See HIP Shot.

SHOT, *Water*. See WATER Shot.

SHOT of a Cable, on *Ship-board*, is the splicing of two cables together, that a ship may ride safe in deep waters and in great roads, for a ship will ride easier by one shot of a cable, than by three short cables out a-head.

SHOT-FLAGON, a sort of flagon somewhat bigger than ordinary, which, in some counties, particularly Derbyshire, it is the custom for the host to serve his guests in, after they have drank above a shilling.

SHOTS, in *Agriculture*, a term provincially applied to young store-swine.

SHOTT, in *Geography*, a town of Egypt; 3 miles S. of Siut.

SHORT, a large valley or plain of Africa, in the country

of Sahara, on the borders of Algiers; 50 miles in length, and about 12 in breadth. The word commonly signifies the sea-shore, or the banks of some lake or river; but the meaning here is somewhat varied, and denotes the borders or area rather of such a plain, as, according to the seasons of the year, is either covered with salt, or overflowed with water. Several parts of the Shott consist of a light oozy soil, which, after sudden rains, or the overflowings of the adjacent rivers, are changed into so many quicksands, and occasion no small danger to the unwary traveller. La Croix was badly informed, in affirming that all the rivers of this kingdom run from south to north: since, besides several others in a quite contrary direction, we have no fewer than five, and those very considerable streams, which empty themselves from the northward into the Shott; 100 miles S.W. of Constantinople.

SHOTTEN HERRINGS. See HERRING.

SHOTTEN, *Blood*. See BLOOD-Shotten.

SHOTTSWOOD, in *Geography*, a town of America, in New Jersey, on the Rariton; 4 miles E. of Brunswick.

SHOVEL, Sir CLOUDESLEY, in *Biography*, a British naval hero, was born about the year 1650, of parents in rather humble circumstances, but who having expectations from a relation, whose name was Cloudesley, they thought fit to bestow that name on their son, as a probable means of recommending him to his relation's notice. Nevertheless, being perhaps disappointed in their plans, they put out their son apprentice to a shoe-maker, to which business he applied some years, when he betook himself to the sea, under the protection of sir John Narborough, with whom he went out in no higher capacity than that of cabin-boy. He soon, by talents and steady application to the art of navigation, became an able seaman, and obtained preferment, through the favour of sir Christopher Myngs. After the close of what is called, in history, the second Dutch war, Shovel went out with sir John Narborough, who was deputed to check the piratical state of Tripoli. In the spring of 1674 sir John arrived before Tripoli, and being ordered to try negotiation rather than force, he sent Shovel with a message to the Dey, desiring reparation for the evils already sustained, and security for the time to come. The Dey, despising his youth, treated him with disrespect, and sent him back with an equivocal answer. Mr. Shovel, on his return, proved that he had not been an unobservant spectator on shore; and the admiral, pleased with his remarks, sent him again with a second message. He was treated with more rudeness than before, which he bore with apparent submission, and made use of it as an excuse for remaining longer on shore; and on his return he assured the admiral, that it was very practicable to burn all the ships in the harbour. Sir John immediately appointed him to the enterprise, which he executed with the most complete success. The account which the admiral sent home respecting the conduct of this young man was so honourable to his talents and courage, that in the course of a few months he had the command of the *Sapphire*, a fifth-rate, given him; and soon after was raised still higher in the service, by being appointed to the *James Galley*, a fourth-rate, in which he continued to the death of king Charles II., by whom he had been raised.

By James II. captain Shovel was preferred to the command of the *Dover*, a fourth rate, in which he was at the time of the revolution. This event was fortunate for captain Shovel, as well as very agreeable to his way of thinking; for being in almost every engagement during the reign of William, he became conspicuous, and made his rise in the service as quick as it was possible to be effected. He was in the battle of Bantry-Bay, in the *Edgar*, a third-rate, and

gave such signal marks of courage and conduct, that when the king came to Portsmouth, he was pleased, on the recommendation of admiral Herbert, who for that action was raised to the dignity of earl of Torrington, to confer on him the honour of knighthood; a title which was, by being more select, of much more worth than it now is. In June, 1690, sir Cloudefley Shovel was employed in conveying the king and his army into Ireland. William, for his good conduct on this occasion, appointed him rear-admiral of the blue, and delivered to him the commission with his own hands.

In the following year sir Cloudefley Shovel attended the king to Holland; and in 1692 he was declared admiral of the red, and again accompanied his majesty to Holland; and on his return he joined admiral Ruffel with the grand fleet, and had a large share in the danger and glory of the celebrated battle of La Hogue. When it was thought requisite that the fleet should be put under command of joint admirals in the succeeding year, he was one; and, says the judicious and cautious Campbell, "if there had been nothing more than this joint commission, we might well enough account from thence for the misfortunes which happened in our affairs at sea, during the year 1693." The joint admirals were of different parties; but as they were all good seamen, and probably meant well to their country, though they did not agree in the manner of serving it, it is most likely "that, upon mature consideration of the posture things were then in, the order they had received from court, and the condition of the fleet, which was not either half manned or half victualled, the admirals might agree that a cautious execution of the instructions which they had received was a method as safe for the nation, and more so for themselves, than any other they could take." On this occasion sir Cloudefley Shovel was at first an object of popular odium; but when the affair came to be strictly investigated in parliament, he gave so clear and satisfactory an account of the matter, that it satisfied the people that the commanders were not to blame; and that if there was treachery, it must have originated in persons in office at home. The character of sir Cloudefley remaining unimpeached, we find him again at sea, in 1694, under lord Berkley, in the expedition to Camaret-bay, in which he distinguished himself by his dextrous embarkation of the land forces, when they failed on that unfortunate expedition; as also when, on their return to England, it was deemed necessary to send the fleet again upon the coast of France, to bombard Dieppe, and other places. From this time till 1702, Shovel was not engaged in any expedition of moment, when he was sent to Vigo, after the capture of that place by sir George Rooke, to bring home the spoils of the Spanish and French fleet. He arrived on the 16th of October, and carried off whatever could possibly be brought home, burnt the rest, and arrived safely in the Downs on the 7th of November; which was considered as so remarkable a service by the court, that, though he was no favourite at court, it was resolved to employ him in affairs of the greatest consequence; and he so effectually crushed the power of the French at sea, that they did not afterwards dare to meet the British fleet; and on account of the great share which he had in the victory obtained the 13th of August 1704, he was appointed rear-admiral of the fleet of England in the January following. He performed many other acts, which were useful to his country, and important to the cause in which it was then engaged. His last act was the defence of the coasts of Italy, of which, when he had taken due care, he left a sufficient force at Gibraltar for the purpose, and set sail with ten ships of the line, five frigates, four fire-ships, a sloop,

and a yacht, for England. On the 22d of October, 1707, he came to soundings, and in the following morning he had ninety fathom water. About noon he lay by, but at six in the evening he made sail again, and stood away under courses, believing that he saw the light on St. Agnes, one of the islands of Scilly. Soon after this several of his ships made signal of distress, as he himself did. It was with difficulty that sir George Byng, in the Royal Anne, saved himself, having one of the rocks under her main chains. Several others run the most imminent risks; but the admiral's ship, and some more, perished with all aboard. How this accident happened has never been properly accounted for. The body of sir Cloudefley Shovel was thrown ashore the next day upon the island of Scilly, where, falling into the hands of some fishermen, he was stripped and buried. Among their plunder was an emerald ring of great value, which, being shewn about, made a great noise all over the island, and led to the discovery of the body. This was now taken up, and conveyed to London, when it was interred with great solemnity in Westminster Abbey. To his memory an expensive monument of white marble was erected, by direction of her majesty, on which was the following inscription: "Sir Cloudefley Shovel, knt., rear-admiral of Great Britain, admiral and commander-in-chief of the fleet; the just rewards of long and faithful services, he was deservedly beloved of his country, and esteemed, though dreaded, by the enemy, who had often experienced his conduct and courage. Being shipwrecked on the coasts of Scilly, in his voyage from Toulon, on the 22d of October 1707, at night, in the 57th year of his age. His fate was lamented by all, but especially the sea-faring part of the nation, to whom he was a very worthy example. His body was flung on the shore, and buried with others in the sands; but being soon after taken up, was placed under this monument, which his royal mistress has caused to be erected, to commemorate steady loyalty and extraordinary virtues." See Stockdale's edition of Campbell's Lives of the Admirals.

**SHOVEL**, in *Agriculture*, a well-known implement, consisting of a long handle, and a broad blade, with raised edges.

**SHOVEL**, *Castling*, a tool somewhat of the wooden shovel kind, which is sometimes employed in cleaning or dressing corn. It is very useful in this mode, where the wind is trusted to for managing the business.

**SHOVEL**, *Draining*, a sort of tool of this nature, frequently employed for the purpose of clearing out the loose crumbly earthy materials from the bottom parts of drains. It is formed with a crooked handle, the edges of the shovel part being turned up on the sides, in order to prevent the materials which are scraped up from falling off. In consequence of the crookedness of the handle, the workman is prevented from stooping so much as would otherwise be the case, in performing the work. There are different constructions of this implement made use of, in managing businesses of this sort.

A scoop is likewise sometimes made use of, both with and without this implement, for the purpose of scooping up and clearing out all the crumbs, loose mould, and other similar materials, from the bottom parts of drains, before they are laid or filled with spray, brush-wood, or any other substance, in order that they may be quite clear and free of any sort of obstruction. The tool is formed in a crooked scoop-like manner at the head, and of different shapes, sizes, and breadths, according to the nature of the drains and openings in which it is to be employed; being, in working, drawn or pushed along the bottoms of the cuts or drains.

The

The handle has also occasionally a crooked form, in order to ease the workman in using it.

**SHOVEL, *Paring***, that sort of tool of this kind, which is employed in some places for paring off the sward or turf from the surface of ground, in order to burn it. The shovel which is used in Devonshire for this purpose has a hollow heart-shaped form in the shovel part, with a long handle, which makes it a very powerful implement. The plate of the mouth part is from nine to ten inches in width, where the handle is inserted, which is made with a considerable curve upwards; the blade is about twelve inches in length, terminating with a broad angular point, which, with its sides, are constantly kept very sharp and keen for cutting; on the left hand, or land side of the tool, a sharp wing, comb, or coulter, rises up in an oblique manner, to cut and divide the slice part from the whole ground. This, however, in consequence of the toughness of the surface, and the impediments presented by the roots of furze, flags, heather, and other similar matters, is not unfrequently dispensed with; the slice being rent or torn off by the workman from the side of the whole ground, while it is cut up and separated from the earth below. When a foot or fifteen inches of the slice rises upon the handle of the shovel, it is separated from the uncut part of the surface by a sudden effort or exertion with the tool, and by a turn of it is whelmed or laid over the mould side upwards. Where the state and circumstances of the surface will permit, as by not being too much loaded and encumbered with the above sorts of plants, the effort of separating the cut from the uncut sward may in all cases be much lessened, by having the slice, which is next to be pared, cut or nicked in such lengths as may be most convenient to the workmen. And in some particular places and situations of land, the regular nicking of the slice to be pared from the ground is indeed found indispensibly necessary, as where the ground is of such a moory quality as to render the operation impracticable without it. In all such instances it is, however, probably much better, as being more convenient and expeditious, to have the shovel formed with a cutting wing, by which the whole may be done at once, without any sort of delay in the business. This sort of shovel may be seen at *fig. 9*, in the plate of paring ploughs.

**SHOVEL, *Spit***, an useful tool for some small purposes. It is that sort which is often employed in setting small roots or plants, as those of the cultivated saffron, and some others of a similar nature.

**SHOVELER**, in *Ornithology*. See *Broad-beaked Duck*.

**SHOVELING**, in *Agriculture*, a term used in Ireland to signify the throwing the mould of furrows, in cleaning them out, over the ridges.

**SHOULDER, HUMERUS**, in *Anatomy*. See *EXTREMITIES*.

**SHOULDER, *Fracture of***, in *Surgery*. See *FRACTURE*.

**SHOULDER, *Luxation of***. See *LUXATION*.

**SHOULDER-Blade**, in *Anatomy*, a bone of the shoulder, of a triangular form, covering the hind part of the ribs, called by anatomists the *scapula* and *omoplatra*. See *EXTREMITIES*.

**SHOULDER-Bone**. See *EXTREMITIES*.

**SHOULDER**, in the *Manege*, is the joint of a horse's fore-quarters, that joins the end of the shoulder-blade with the extremity of the fore-thigh.

**SHOULDER of a Branch**, is that part of it which begins at the lower part of the arch of the banquet, over-against the middle of the fonceau or chaperon, and forms another arch under the banquet. The shoulder of a branch calls a

greater or lesser circumference, according as it is designed to fortify or weaken the branch. See *BRIDLE, BANQUET, and BRANCHES*.

**SHOULDER-Pegged Horses**, called in French *chevilles*, are such as have their shoulders gourdy, stiff, and almost without motion. A horse charged with shoulders, is one that has thick, fleshy, and heavy shoulders.

**SHOULDER of a Bastion**, in *Fortification*, is where the face and the flank meet.

**SHOULDER-Drain**, in *Agriculture*, a sort of under drain, constructed with a shoulder on each side of the cut or opening, so that some sort of strong substance may be laid over it, and form an opening or drain for the water below. See *DRAIN*.

**SHOULDER**, in *Block-Making*, a projection made upon the surface of blocks, pins, &c. by reducing one part to a less substance.

**SHOULDER-Block**, a large single block, left nearly square at the lower end, or arse of the block, and cut sloping in the direction of the sheave. Shoulder-blocks are used on the lower yard-arms, to lead in the top-sail-sheets, and on the top-sail-yards, to lead in the top-gallant-sheets; and by means of the shoulder they are kept upright, and prevent the sheets jamming between the block and the yard: they are also used at the lower outer end of the boomkins, to lead in the fore-tacks.

**SHOULDER-of-Mutton Sail**, a triangular sail, similar to the lateen sail; but attached to a mast instead of a yard.

**SHOULDERING**, in *Fortification*. See *EPAULEMENT*.

**SHOULDERING-PIECE**, in *Building*. See *BRACKET*.

**SHOULDER-KNOTS**. See *EPAULETTES*.

**SHOULDER-PITCHT**, in *Ferriery*, is a disease in a horse, when the pitch or point of the shoulder is displaced, which makes the horse halt downright.

**SHOULDER-SPLAIT**, or **SHOULDER-TORN**, is a hurt which befalls a horse by some dangerous slip, by which the shoulder is parted from the breast.

**SHOULDER-WRENCH**, is a strain in the shoulder.

**SHOUT, CLAMOR**, in *Antiquity*, was frequently used on ecclesiastical, civil, and military occasions, as a sign of approbation, and sometimes of indignation. Thus as Cicero, in an assembly of the people, was exposing the arrogance of L. Antony, who had had the impudence to cause himself to be inscribed the patron of the Romans, the people, on hearing this, raised a shout to shew their indignation.

In the ancient military discipline shouts were used, 1. upon occasion of the general's making a speech, or harangue, to the army from his tribunal: this they did in token of their approving what had been proposed. 2. Before an engagement, in order to encourage and spirit their own men, and fill the enemy with dread.

This is a practice of great antiquity, besides which, it wants not the authority of reason to support it, for as mankind are endowed with two senses, hearing and seeing, by which fear is raised in the mind, it may be proper to make use of the ear as well as the eye for that purpose.

Shouts were also raised in the ancient theatre, when what was acted pleased the spectators. See *ACCLAMATION*.

It was usual for those present at the burning of the dead to raise a great shout, and call the dead person by his name before they set fire to the pile. See *BURIAL*.

**SHOWEL**,

**SHOWEL**, in *Agriculture*, a term applied to a blind for a cow's eyes.

**SHOWER**, a cloud resolved into rain, and discharged on a certain tract of ground.

In *Natural History* we meet with abundance of instances of extraordinary and preternatural showers; as *showers of blood*, mentioned by Gallendus and others; a *brimstone shower*, mentioned by Wormius; *showers of frogs*, mentioned by Pliny, and even by Dr. Plott; a *shower of millet-seed* in Silesia, mentioned in the *Ephem. German.*; *showers of ashes*, frequent in the Archipelago; a *shower of wheat*, in Wiltshire; a *shower of whittings*, mentioned in *Philosoph. Transact.* The natural reasons of many of which may be seen under **RAIN**.

**SHOWOOR**, in *Geography*, a town of Hindoostan, in Myfore, where, in 1790, a bloody battle was fought between the British and Tippoo, and in which the latter was defeated; 15 miles S. of Sattimungulam.

**SHOWS**, or **SHAWS**, in *Agriculture*, a term applied to the haulm or tops of potatoes. See **POTATOE** and **SOLANUM**.

**SHRAHEEN**, in *Geography*, a mountain of Ireland, in the county of Mayo; 11 miles N.N.E. of Castlebar.

**SHRAVEY LAND**, in *Agriculture*, a term used in some districts, as those of Suffex, and some others, to signify that of a strong, gravelly, or flinty nature. The scars or holes on the sides of steep hills, where the turf or sward has slipped away, and laid bare the soil on the South Down, are sometimes called shraives. See **SOIL**.

**SHREW**, or *SHREW-Mouse*, in *Zoology*, the common name of the creature called by authors *Mus araneus*, and *Sorex araneus* of Linnæus. It is an animal of a mixed brown and reddish tawny colour: the belly is white; its tail is about one inch and a half long, and covered with short hairs; its body is about two inches and a half in length; and its eyes black and very small; they are indeed little larger than those of the mole, and do not exceed the size of the head of the smallest pin; it is no wonder, therefore, that the creature is almost blind; the nose long and slender; the ears short and rounded: the teeth are very small, and differ in their shape and situation from those of all other creatures in the world; and seem as if nature had in one creature made a sort of mixture of the teeth of the mouse and the snake kind.

It has two long fore-teeth, as all the mouse kind have: but these are not single, as in mice, but have two or three other small and sharp teeth growing out of them: these, to an accurate observer, might either be wholly unseen, or taken for distinct teeth; and the anterior long teeth are not separated from the rest by any gap or space, as in the mouse kind, but make one continued series with the others. The upper jaw in this creature is longer than the under, and the teeth are sharp and ferrated, some with two, some with three points, and these so small, that they might easily not be seen, but that the tips of them are reddish. Their whole number is twenty-eight.

It is very common in many parts of the world, and is met with in almost all our dry grounds, in old walls and holes in the earth; near hay-ricks, dung-hills, and necessary houses; it lives on corn, insects, and any filth; the cats will kill it, but never attempt to eat it. It brings four or five young at a time.

Its whole body has a fetid and offensive smell. The ancients erroneously believed it was injurious to the cattle. There seems to be an annual mortality of these animals in the month of August, numbers being then found dead in the paths.

It is distinguished at first sight from the common mouse, in that it is smaller; its nose longer, and like a hog's; it has five toes on the hinder as well as the fore-feet; its eyes are extremely small; its ears very short; its claws are long and whitish, and its feet short. Ray and Pennant.

*SHREW-Mouse, Water, Sorex fodiens* of Pallas, is much larger than the common shrew; its length from nose to tail being  $3\frac{3}{4}$  inches; its tail two inches; the upper part of the body and the head are of a black colour; the throat, breast, and belly, of a light ash-colour; and beneath the tail there is a triangular dusky spot.

This animal inhabits Europe and Siberia; was lost in England till the year 1768, when it was discovered in the Lincolnshire fens; it burrows in the banks near the water, and is said to swim under water; it is called in some places the *blind mouse*, on account of the smallness of its eyes; and it chirrup like a grasshopper. Pennant.

**SHREWSBURY**, in *Geography*, an ancient borough and market-town in the hundred of the same name, and county of Salop, or Shropshire, England, is situated on two hills, peninsulated by the river Severn, at the distance of 112 miles from Bath, and 162 miles from London. It is the chief town, or capital, of the county, and, from its historical importance, is particularly deserving of an extended description, even in a work like the present. According to the parliamentary returns of 1811, it is divided into the six parishes of St. Giles and Holy Cross, St. Chad, St. Mary, St. Julian, St. Alkmund, and Meole-Brace, which united, contain 3229 houses, and 16,606 inhabitants. It must be remarked, however, that some of these parishes extend a short way into the country. The liberties of Shrewsbury comprise six other parishes, four townships, and two chaptries.

*Origin and Historical Events.*—Although no doubt can be entertained of the high antiquity of Shrewsbury, it being frequently mentioned by our earliest historians, there is no authentic record of its origin. Probable conjecture, however, has assigned that event to the fifth century, when the Britons were forced by the Saxons to abandon all the country to the eastward of the river Severn. It is supposed that, after the destruction of the Roman Uriconium, the fortifications of which enabled the possessors for a time to check the progress of their enemies, that they established themselves on the site of Shrewsbury, on account of the natural security afforded by its lofty and peninsular position. At that period this spot was called the Pengwerne hill, whence the town received the appellation of Pengwerne, to which Powis was subsequently added, when it had become the capital of Powisland, and the seat of its princes, whose palace occupied the same ground with the old church of St. Chad. Here the Britons maintained themselves for several centuries, notwithstanding the repeated efforts of the Mercian Saxons to dispossess them; but at length the arms of the warlike Offa proved too powerful for further resistance, and they were compelled to retire to Mathrafael, among the mountains of Montgomeryshire, where they preserved their ancient dignity and independence, till finally subdued by Edward I. of England.

The Saxons, having obtained possession of this ancient capital, changed its name from Pengwerne to Scrobbebyrig, or Scrobbebyri, which words have nearly the same signification, *viz.* "the head of the alder groves." Instead of levelling it with the ground, as was their custom when they seized upon any British town, they seem to have protected it with care, and probably even increased its opulence and extent. In the reign of Alfred it was numbered among the principal cities in his dominions: and in that of Edward the Elder

## SHREWSBURY.

Elder it had the privilege of a mint. In 1006, king Ethelred kept his Christmas here; but in about ten years thereafter, the inhabitants having declared against that prince in favour of his rival Canute the Dane, his son, prince Edmund, afterwards king Edmund Ironside, attacked and took the town after a short siege. On this occasion Shrewsbury seems to have suffered greatly; as in the reign of Edward the Confessor, its houses only amounted to 252 in number. Posterior to the Conquest, it was bestowed upon Roger de Montgomery, who was created earl of Shrewsbury, Arundel, and Chichester; and appears from Domesday book to have then paid 20*l.* in taxes to the king and sheriff. Earl Roger, on acquiring possession of this city, (for so it was styled in his time,) fixed his residence in it, and founded both a castle and an abbey. He did not, however, long possess them undisturbed, for in 1067, Owen Gwynnedd, prince of Wales, assaulted it with so formidable a force, that the conqueror deemed it advisable to repel the invasion in person. He accordingly marched hither from York, raised the siege, and overthrew the Welsh with prodigious slaughter. Shrewsbury was again besieged in the reign of Henry I., in consequence of its then possessor, Robert, son to earl Roger, having united his forces to those of the rebellious barons; and it was probably only saved from the horrors of an assault by the submission of the earl, who was banished to Normandy, and had all his immense estates forfeited to the crown.

Shrewsbury being esteemed the most important town and fortress on the marches of Wales, continued, during several centuries, to be one of the principal places of rendezvous for the English armies, and hence was often visited by its monarchs. Numerous conflicts took place in its immediate vicinity, and its inhabitants frequently suffered the evils incident to sieges. During the wars between Stephen and the empress Maud for the succession to the crown, William Fitz-Alan, a powerful baron, then governor of Shrewsbury castle, supported the claims of the latter. Stephen, however, early obtained possession of it, and ungenerously put to death many of the brave knights by whom it was defended. Fitz-Alan fled to the continent, where he remained an exile till the accession of Henry II., who restored him to all his honours and possessions. In the reign of king John, the royal council assembled here to consider of the best means of checking the incursions of the Welsh; when the prince of Powis came, and frankly offered terms of accommodation: but to the disgrace of the English lords, instead of receiving him with respect, they threw him into prison. Soon afterwards, however, he was released, and a treaty with the Welsh was concluded, for the performance of which twenty-nine children were delivered as hostages, all of whom were most inhumanly hanged by king John, in consequence of some infringement of its terms by the prince of Wales. But this barbarous massacre did not long remain unpunished; for in 1215, the Welsh having dispersed all the armies of the lords marchers, suddenly appeared before Shrewsbury, which submitted without resistance. How long the Welsh held their conquest, or how they lost it, is uncertain; but in 1221 Shrewsbury had again passed into the possession of the English. In the seventeenth year of Henry III. it was plundered and burnt by the earl of Pembroke and other factious barons, who had joined their arms to those of prince Llewellyn. The rebel Simon de Montfort, earl of Leicester, likewise seized upon this town; but it soon reverted to the king: and in 1267, Henry assembled a large army here, with the design of crushing the Welsh power, but the interference of the pope prevented the execution of his views. Edward I., who, during his father's life-time, had

been invested with the government of Shrewsbury, made it, in 1277, the principal seat of his court, and removed hither the courts of exchequer and king's bench, that he might the more easily accomplish his favourite object, the subjugation of Wales.

During the rebellion which the infatuated attachment of Edward II. to the Spencer family gave rise to, the king was received at Shrewsbury with great military parade, and a tournament was held here, attended by the knights and soldiers of the marches. Afterwards, when Edward was deprived of his liberty and throne by his queen, and her paramour, Roger Mortimer; Edmund Fitz-Alan, earl of Arundel, who had been faithful to his allegiance, was seized by the inhabitants, and put to death; for which service Mortimer, in the name of the king, granted to the burghesses of Shrewsbury, whom he calls "the good men of Salop," all the goods and chattels found upon the earl. Richard II. held a parliament here in the 20th year of his reign, on which occasion he gave a sumptuous feast to the members in the abbey of St. Peter and St. Paul. The next event of importance which occurred at this town was the famous battle of Shrewsbury, in which Henry V., then prince of Wales, first distinguished himself in the field, and the gallant Hotspur fell, after performing, in conjunction with his rival Douglas, the most brilliant acts of prowess.

Throughout the whole of that eventful period, marked by the contentions of the rival houses of York and Lancaster, the inhabitants of Shrewsbury steadily adhered to the interests of the former. The learned author of the "Account of the ancient and present State of Shrewsbury," contends that it was here, and not at Salisbury, as commonly supposed, that Henry Stafford, duke of Buckingham, was executed by order of Richard III., who was chiefly indebted to him for his usurped crown. When Henry VII. landed in Wales, he marched directly towards Shrewsbury, where he was received "with raptures of joy" by all except the "head bailey," who for a time refused him admittance. Here he was first proclaimed king of England, and here he collected and organized the greater part of those forces with which he achieved the signal and decisive victory of Bosworth Field. In consequence of these circumstances, Shrewsbury was greatly favoured by that monarch, and was frequently visited by him during his reign.

From this period till the reign of Charles I. no event of historical importance happened here. When the parliamentary war broke out, however, the king came hither, and was cordially welcomed by the inhabitants, though they had been strongly prejudiced against him by the commissioners for the parliament. The greater part of the army with which he first took the field was composed of persons resident in this town and the adjoining counties. After the king left Shrewsbury, it was garrisoned in his cause; but the bad health of the governor having prevented him from enforcing the discipline of the soldiery with sufficient vigour, they became negligent and debauched. The parliamentary officers, colonels Mitton and Bowyer, being informed of the state of the garrison, made several attempts to surprize the town, and at length succeeded in their object, in February 1645. By this event the parliament gained the important advantage of cutting off the king's communication with North Wales, and a formidable association, which was on the point of being formed between the loyal inhabitants of the counties of Salop, Worcester, Cheshire, and Flint, was destroyed in the bud.

In Cromwell's life-time, and also immediately after his death, two attempts were made to gain possession of Shrewsbury in favour of Charles II.; but both of them were frustrated. The last circumstance which history records worthy of notice, occurred

## SHREWSBURY.

occurred in August 1687, when James II. held his court here. On this occasion, the "sentiments of loyal attachment, for which Shrewsbury has ever been conspicuous, burst forth with chivalrous enthusiasm."

*General Appearance of the Town.*—Shrewsbury, from its lofty and peninsular situation, presents, at every approach, a pleasing variety of views; "and the noble sweep of the river, which seems to embrace it, heightens at every turn the charms of the scene." Except on the north and west sides, where the streets approach close to its banks, a narrow margin of meadow, or of garden ground, interposes between the houses and the river. The exterior circle of the town is lined with an unbroken range of well-built houses, most of which command beautiful views over the adjacent country. On its western side is a public field, called the Quarry, which occupies about twenty acres of ground, and is adorned with avenues of trees. At one extremity of this field are the remains of a rural amphitheatre, where the Augustine friars of the adjoining convent were probably wont to exhibit those ancient sacred dramas called mysteries, or Whitsun plays; which were certainly acted here in the reign of queen Elizabeth.

Such is the exterior aspect of Shrewsbury; but it is to be regretted that its interior appearance is far from corresponding with the external aspect. The streets are ill arranged, and some of them narrow and steep, and but indifferently paved. The houses are extremely mixed in their architectural character, exhibiting a strange contrast of ancient and modern buildings. This circumstance is in part to be attributed to the happy freedom which Shrewsbury has enjoyed, from those general conflagrations which have occasionally devastated other towns within the last two centuries.

*Civil Government and Corporation.*—Shrewsbury is a corporation, both by charter and prescription. The first charter was granted by Henry I.; but other princes have since altered and extended the privileges it conferred. By the charter now in force, granted by king Charles I., the corporation consists of a mayor, recorder, steward, town-clerk, 24 aldermen, 43 assistants, or common councilmen, two chamberlains, a sword-bearer, serjeants at mace, &c. Four general quarter-sessions are held in the course of the year, and the mayor and some of the aldermen, who are magistrates, hold a court every Tuesday. The chartered companies, besides the general corporations, are sixteen in number, of which those of the drapers and mercers are the most considerable.

Shrewsbury sent members to parliament from their earliest establishment. They are chosen by the inhabiting burgesses, who have been legally assessed to the parish rates. The mayor is the returning officer. The markets are on Wednesday and Saturday, weekly; and there are eight annual fairs.

*Public Buildings and Institutions.*—The public structures of Shrewsbury are, the castle, the town-hall, the churches, the charitable institutions, the town and county gaol and Bridewell, the market-house and cross, the theatre, and the bridges.

The *Castle* stands on a narrow neck of land, about five hundred yards in breadth, which is formed by the windings of the Severn. It was founded by Roger de Montgomery, as before mentioned, and became the chief seat of his baronial power. As all the transactions of interest connected with this edifice have been noticed under the head *Historical Events*, &c. it is unnecessary to repeat them. This structure has evidently undergone so many alterations, and is so greatly dilapidated, that it is difficult to form any probable idea of its ancient state. The buildings of it now remaining

consist of the keep, the walls of the inner court, and the great arch of the interior gate-way. The keep, which is converted into a handsome dwelling-house, consists of two round towers of equal size, embattled and pierced, and connected by a square building, about one hundred feet long, and nearly of the same height. The inner court is now a garden, "on a circular grass-plot in which the newly elected knights of the shire have been girt with their swords by the sheriff, from perhaps the first foundation of our invaluable constitution." The arch of the gateway is clearly part of the original castle. It is eighteen feet high, massive, and semi-circular, and appears to have supported a tower, from which hung the portcullis. On the opposite side of the court is a small postern, probably built in the time of Charles I.; and on its south side is a lofty mount, the summit of which is surrounded by a ruined wall, at one part of which rises a small watch-tower, now a beautiful summer room, much resorted to on account of the fine views which it commands. This castle was defended by ramparts of stone thrown across the peninsula, from the castle to the river, on each side. One of them was formed by Robert de Belesme, and the other by order of Oliver Cromwell. Ramparts and walls with towers likewise defended the town on its northern and eastern sides, but few traces of these remain. The principal gates were three in number, and called the Castle or North-gate, the East or Abbey-gate, and the Welsh-gate, the latter of which stood on the Welsh bridge.

The *Town-hall* is a modern structure, finished in 1786. It was designed by Mr. Haycock, a native of the town, and exhibits a handsome stone front. Here are held all meetings of the corporation, and grand juries, likewise the courts of justice for the town and county. The grand jury room is decorated with portraits of George I. and II., and of admiral Benbow; and another room is appropriated to the reception of a valuable collection of books.

The *established churches* are St. Giles's, St. Chad's, St. Mary's, St. Alkmund, and St. Julian's. St. Giles's is a small plain building, and appears, from some remains of massive square piers, and a semi-circular arch, to have been partly built in the Norman era, and probably on a larger scale than it is at present. Most of the other piers are round, and support pointed arches. St. Chad's church is of modern erection, having been built between 1790 and 1792, in lieu of the old collegiate church, which fell down in the first mentioned year, in consequence of its repair having been too long neglected. It is, "upon the whole, a splendid, and, in many respects, an elegantly ornamented structure." In this church the mayor and corporation are accustomed to sit on festival and other public days. Here are but few monuments, and none of note; but in the church-yard is a chapel, in which many of the tombs and inscriptions rescued from the ruins of the old church are deposited; the principal of them, however, were removed to the respective parish-churches of the families to which they belonged. St. Mary's church was likewise collegiate, and had the privileges of a royal chapel, of which advantages it was deprived in the reign of king Edward VI. It is a venerable pile, in the form of a cross, and comprises a nave, side-aisles, transept, choir, and chapels, with a tower at the west end. Its architecture embraces almost every style prevalent from the Norman conquest to the reign of Henry VIII. The nave is divided from the side-aisles by semi-circular arches; but those separating it from the choir are lofty and pointed. The ceiling here is of oak, and rises in an extremely flat arch, divided by its principal beams into square panels, including circles richly adorned with quatre-foils and foliage; the ribs and bosses being carved into double roses, with devices and knots at their intersection.

## SHREWSBURY.

perfection. The chancel, choir, &c. display chiefly the pointed style. At the extremity of the former is a spacious window, in the later pointed style, which is nearly filled with stained glass, brought from the ruins of old St. Chad's church. The principal piece represents Jesse in a deep sleep. The spire of this church rises 217 feet above the summit of the tower, upon which it rests. The monuments are numerous, and some of them curious: but we shall only notice one inscription, which is remarkable, from the circumstance of its commemorating a person named Cadman, who was killed in descending from the summit of the spire, by a rope slanting from thence to the opposite side of the river from that on which the church stands. The parish-church of St. Alkmund's, like the two last mentioned, was formerly collegiate, but its college was dissolved as early as the reign of king Stephen. The old church was taken down about the year 1793, and the present building raised in its stead, which is a clumsy imitation of our ancient architecture. St. Julian's church, which closes the list, is a plain substantial edifice, rebuilt in 1750, on account of the ruinous condition of the former edifice.

In addition to the above established churches, there are in Shrewsbury several dissenting places of worship, *viz.* a Roman Catholic chapel, a Presbyterian meeting-house, also one for Methodists, and another for Quakers.

The *Charitable Institutions* belonging to Shrewsbury are, a small hospital, formerly dedicated to St. Giles, another called Millington's hospital, several alms-houses, an infirmary, a house of industry, and the free and charity-schools. The infirmary is among the earliest provincial institutions of the kind in England, having been opened in 1747. It is supported by voluntary subscriptions, and by benefactions. The house is a plain but respectable building of brick, with a stone portico in front. The house of industry was originally a founding hospital, connected with that in London, and was only converted to its present purposes in 1784. It is governed by directors chosen from among the inhabitants of Shrewsbury, and maintains, on an average, about 275 poor, including children, partly by a rate levied on the six parishes, and partly by the produce of the labour of the paupers. The free grammar-school was founded and endowed by king Edward VI. at the request of Henry Edwards and Richard Whitaker, and was afterwards augmented by queen Elizabeth, at the instance of Thomas Ashton. The school-house is a large and lofty structure, forming two sides of a square court. The government of this school is vested in the bishop of Lichfield, and the corporation, who appoint two school-masters, one of whom is superior to the other. Several of them have been men of great talents and erudition, and have cherished the seeds of knowledge in many individuals afterwards distinguished in society. Among the latter, were sir Philip Sydney; lord Brook, lord chief justice; lord chief justice Price; Dr. Bowers, bishop of Chichester; Dr. John Thomas, bishop of Salisbury; and the learned Dr. John Taylor. The learned Dr. Butler is the present head master. The other public schools in this town are Bowdler's charity-school, founded in 1724, by Mr. Thomas Bowdler, alderman, for the education and clothing of poor children of St. Julian's parish; Allart's charity-school, founded in 1798, under a bequest by Mr. John Allart, one of the chamberlains of the corporation; and a subscription charity-school, instituted in 1708, for instructing poor children of the town at large.

The *Town and County Gaol and Bridewell*, which now form one building, stands near the castle, where the sheriff probably had his gaol in former times. Its situation is at once beautiful and salubrious, and though it cannot boast much elegance of exterior appearance, it is spacious and

airy, and possesses every convenience requisite for its different purposes. In front is a free-stone arched gateway, containing a bull of Howard, by Bacon.

The *Market-house* is one of the largest and most magnificent buildings of its kind in England. It is of the age of queen Elizabeth, whose arms, sculptured in high relief, decorate the portal, on each side of which is an open arcade, consisting of three large circular arches, supported by columns. The north and south ends of the building are likewise ornamented with large open arches, over one of which stands a statue of Richard, duke of York, removed hither from the Welsh bridge in 1791. Adjoining this building is a conduit, which supplies a great part of the town with water. The *Market-cross* is a strong structure of brick and stone, having a reservoir over it. The old cross was destroyed in 1705. The *Theatre*, according to Phillips, the old historian of the town, is part of the palace formerly belonging to one of the later princes of Powis, but though evidently an ancient structure, it seems improbable that its date should be so remote as such a fact would necessarily imply. It is fitted up in the interior in an appropriate manner.

The *Bridges* over the Severn at this town are called the Welsh bridge, and the English, or East, bridge. Both of them are new structures, erected in place of older ones, which had gone to decay, and were, from their narrowness, unsuitable to the state of commercial advancement Shrewsbury and the county at large now enjoy. The Welsh bridge consists of five elegant arches, about 266 feet in aggregate length, 30 feet high, and 30 broad. Adjoining to it is a quay, faced with stone, and accommodated with warehouses. The English bridge extends 400 feet in length, and consists of seven semi-circular arches, built of fine free-stone. The central arch is 60 feet span and 40 high from the low-water mark; and the two on each side 35 feet wide and 20 high. The breadth between the ballustrades is 25 feet; and the ornaments are at once light and graceful.

*Monastic Institutions.*—The principal monastic establishment in Shrewsbury was the abbey of St. Peter and St. Paul, which stood in the suburb that still bears its name. It was founded, or, as some will have it, refounded and endowed by Roger de Montgomery, and a nobleman named Warine, who filled it with monks of the Benedictine order. These having subsequently obtained possession of the relics of St. Winefrid, their abbey became the constant resort of various classes of people from all parts of the kingdom, who, according to their circumstances, offered donations on the shrine of the saint. This society, at its dissolution, consisted of an abbot, fourteen monks, and three novices, whose annual revenues, according to Dugdale, amounted to 53*l.* 4*s.* 10*d.* but Speed rates them as high as 656*l.* 4*s.* 3*d.* The remains of the abbey are very inconsiderable, the ground which it occupied being in great part converted into a garden. There is, however, a very curious little structure, which has puzzled the learned in antiquities as to its use: by some it is regarded as a pulpit for preaching. Its plan is an octagon, six feet in diameter, but considerably higher. Over it is an obtuse dome of stone, supported by six narrow pointed arches. The roof within is vaulted on eight ribs, which spring from the side walls, and form a boss at their crossing in the centre, bearing a representation of the crucifixion. The arches on the south side are without ornament, but three of them on the north side are filled with stone panels, adorned with different figures of angels and saints. The abbey church was built in the form of a cross, and was a spacious and magnificent edifice; but at present is in a state of dilapidation, except the western aisle, which is now used as a parish-church, instead of St. Giles'. The other reli-

gious houses here were, a convent of Augustine friars, founded about the year 1256; a second of Franciscan or Grey friars, the date of which is unknown; and a third of Dominicans, founded by lady Geneville in the reign of Henry III. The queen of Edward IV. twice lay in at this monastery. Besides these, there were chapels dedicated respectively to St. Michael, St. Nicholas, St. Catherine, St. Blaise, and St. Mary Magdalen.

Shrewsbury contains several ancient private structures, which would claim notice, did the limits of our article permit of a commensurate extension. One of them, still called the Council-House, was formerly the residence of the court of the marches of Wales, on their annual visits to this town. For some account of this court, see LUDLOW.

The eminent natives of Shrewsbury, besides Dr. Thomas and Dr. Taylor, before-mentioned, were Thomas Churchyard, a poet of some note, admiral Benbow, and the Rev. Hugh Farmer, author of several learned and critical works.

The objects in the vicinity of Shrewsbury, most worthy of notice, are the Shelton oak, which is remarkable from a tradition, that Owen Glyndwr ascended it to reconnoitre, previous to the battle of Shrewsbury, and for its great size; Battlefield, where the battle was fought; and Haughmond Abbey, which stands about four miles to the eastward of Shrewsbury. It is situated on a rising ground, which commands beautiful and extensive views, and owed its foundation and endowment to William Fitz-Alan, in the year 1100. The inhabitants were canons regular of St. Augustine, who enjoyed at the dissolution a yearly revenue, stated by Dugdale at 259*l.* 13*s.* 7*d.* and by Speed at 294*l.* 12*s.* 9*d.* Of the abbey-church, scarcely a vestige remains, but considerable portions of the other buildings are yet standing. Phillips' History and Antiquities of Shrewsbury, 4to. Some Account of the ancient and present State of Shrewsbury, 12mo. 1808, an interesting and judicious topographical work. Beauties of England and Wales, vol. xiii. by J. Nightingale and R. Rylance.

SHREWSBURY, a town of America, in the State of New Jersey, and county of Monmouth, on the Sea board, having Middletown on the N., Freehold W., and Dover S.W. It is divided from Middletown by North river, which is navigable for a few miles. The compact part of the town is pleasant, and contains an Episcopal and Presbyterian church, and a meeting-house for Friends. The number of inhabitants is 3773. This place is frequented in summer by genteel company from Philadelphia and New York, for health and pleasure; 79 miles E.N.E. of Philadelphia.—Also, a township of America, in Rutland county, Vermont, between Clarendon on the W. and Saltash on the E., containing 990 inhabitants.—Also, a township of York county, Pennsylvania, containing 1792 inhabitants.—Also, a township in Worcester county, Massachusetts, incorporated in 1727, and containing 1210 inhabitants; 6 miles E. of Worcester.—Also, a town of Pennsylvania, in Codorus creek; 10 miles S. of York.

SHREWSBURY, a river of New Jersey, which runs into the Atlantic, N. lat. 40° 22'. W. long. 74° 2'.

SHRIKE, in *Ornithology*, an English name for several species of the *Lanius*; which see.

SHRILLA, in *Geography*, a town of Africa, in Ludamar; 38 miles E.S.E. of Benown.

SHRIMP, in *Natural History*, is the CANCER *Crangon* of Linnæus; which see.

This shell-fish inhabits the sandy shores of Britain in vast quantities, and is reckoned the most delicious of the genus. Some writers have classed it under the genus of SQUILLA.

The white shrimp, or *cancer squilla*, is the prawn. (See CANCER *Squilla*.) It inhabits the coast of Kent.

By 30 Geo. II. c. 21. white shrimps in the river Thames and Medway are only to be taken from Bartholomew day to Good Friday; and red shrimps in the river Medway only from April 25 to July 1.

SHRINE, formed from *scrinium*, a desk, or cabinet, a case to hold the relics of some saint.

SHRITE, in *Ornithology*. See MISSEL-Bird.

SHROFF, a sort of banker or money-broker in the East Indies. See RUPEE.

SHRONDO, in *Geography*, a town of Africa, in the kingdom of Dentila, in which are considerable gold mines.

SHROPSHIRE, one of the midland counties of England, is situated between 52 and 53 degrees N. latitude, and 2 and 3 degrees W. longitude, from London. It is bounded on the S. by the counties of Worcester and Hereford; on the E. by Staffordshire; on the N. by Cheshire, a detached part of Flintshire, and by Denbighshire; and on the W. by the same county, and those of Radnor and Montgomery. According to archdeacon Plymley's "General View of the Agriculture of Shropshire," it extends about 44 miles in length, 28 in breadth, and 134 in circumference, comprising an area of 890,000 acres, or about a 45th part of England and Wales united. In shape it approaches to that of an oval, and is separated into two almost equal divisions by the river Severn. The parliamentary returns of 1811, state the number of houses it contains at 36,853, and its population at 194,298 persons, of whom 95,842 were males, and 98,456 females.

*Historical Events.*—When the Romans invaded this island in the reign of the emperor Claudian, this county was inhabited by two British tribes, called the Ordovices and Cornavii, whose respective territories were bounded by the Severn. The Ordovices, who appear to have been a most warlike and enterprising people, joined with the Silures, under the renowned Caractacus, to defend their country. Among the hills of Shropshire, that great chieftain for a time successfully strove against the overwhelming tide of Roman conquest; and here, several antiquaries contend, was fought the unfortunate conflict which terminated his military career, and led to his captivity. After that event, Shropshire formed part of the province called Flavia Cæfariensis, and seems to have been held in undisturbed tranquillity so long as the Romans remained in Britain; but when they withdrew their forces to the continent, it again became the theatre of war between the Britons and the Saxons. For some centuries it constituted part of the kingdom of Powisland, of which Pengwern, now Shrewsbury, was the capital (see SHREWSBURY); but in the reign of the great Offa it fell under the dominion of the Saxons, when the British princes retired to Mathrafael, in Montgomeryshire. To secure his conquests, Offa formed an immense rampart of earth, extending about 100 miles in length along the confines of Wales; but the utility of this work, for the purposes of defence, seems to have been very inconsiderable, as we find the Welsh constantly making inroads into the Mercian territories.

In the ninth century, when the Danes invaded this island, Shropshire shared in the calamities which their ferocity brought upon the kingdom, but in a much less degree than most other counties. During the reign of Edward the Confessor, Gruffydd, prince of North Wales, became the terror of the English by his incursions into this county. Harold undertook an expedition against him, in which he was so successful, that the Welsh were glad to purchase peace by the

## SHROPSHIRE.

the massacre of their chief. After the conquest, nearly the whole of Shropshire was bestowed on Roger de Montgomery, a relation of the conqueror's; but the inroads of the Welsh frequently disturbed him in the enjoyment of his splendid acquisitions. In 1067 they laid siege to Shrewsbury, the feat of his baronial power, with so formidable a force, that the king found it necessary to march against them in person, when they were defeated with great slaughter. This discomfiture, however, only served to increase the warlike spirit of the Welsh; and William, finding himself foiled in his repeated attempts to reduce those high-spirited foes to submission by open combat, adopted a more politic mode of warfare. He issued grants to certain of his favourites of all the lands they should be able to conquer from the Welsh; and endeavoured to divide and weaken the Welsh border chieftains themselves, by promising a confirmation of all the rights and privileges to such of them as would simply acknowledge the sovereignty of the English crown. Hence appears to have originated the feignories and jurisdictions of the lord marchers, whose power was even more arbitrary and despotic than that of the monarch himself. They constructed and repaired fortresses at their pleasure, and garrisoned them with soldiers of their own. They likewise built towns, and exercised the most absolute authority, both civil and military, within their respective territories. In later times, however, this power was considerably controlled by a chief court of the marches of North Wales, which was generally held at Ludlow, but sometimes also at Shrewsbury and other towns; and was still more limited after the union of Wales with England, from which period no lord marcher could exercise any prerogative not confirmed to him by charter, without a special licence from the crown. During the various revolts which occurred subsequent to the death of Edward I., and also during the contentions for the crown between the houses of York and Lancaster, Shropshire was occasionally the scene of military contests, of which the most celebrated was the battle of Shrewsbury. When the civil war broke out in the 17th century, this county was peculiarly distinguished for its loyalty; but except the taking of the county-town by the parliamentary forces, no transaction of peculiar interest happened within its limits throughout that unfortunate era.

*General Aspect, Soil, and Climate.*—Shropshire possesses within its boundaries almost every variety of natural charm; the bold and lofty mountain; the woody and secluded valley; the fertile and widely cultured plain; the majestic river, and the sequestered lake. The soil is no less various. In the hundred of Osweltry, a deep loam and gravelly soil prevail; and in those of North Bradford and East Brimstrey, a light or sandy loam. Pimhill hundred contains a mixture of "boggy land, and of sandy soil, with a greater proportion of sound wheat land." In the other hundreds, clays of different consistence form the most general soil; but there are numerous patches and extensive tracts both of deep and sandy loam, gravel, &c. The climate of course partakes of the character of its surface and soil. On the eastern side of the county, where the land is warm and flat, harvest frequently commences a fortnight sooner than near the middle of the county, where the vales are extensive, but the surface less light, and the bottom often clayey; and hay and grain are both gathered earlier there than on the western side, where the vales are narrow, and the high lands frequent and extensive, although the soil is not in general so stiff. The easterly winds prevail most in spring, and those from the west in autumn; but the easterly winds are the most regular; those from the west blowing for a series of months (five

or six perhaps) strong and frequent, and then for nearly a similar period less often and less violent. The same may be said of the wet and dry seasons in this county, but the periods of both appear to be much shorter.

*Rivers and Lakes.*—Shropshire abounds with rivers as much as any county in England. The principal among them is the Severn, which, after bounding the county for several miles, enters it near Melverley, and flows on in an irregular serpentine channel to Shrewsbury, which it nearly encircles. At this town it turns towards the north, but soon again sweeps to the southward, passing by Wroxeter, Madeley, and Bridgenorth, to Bewdley, where it enters Worcestershire. Its course within Shropshire is estimated at nearly seventy miles in length, throughout the whole of which space it is navigable for barges, trows, wherries, and boats, and is abundantly supplied with fish of various denominations. The contributory streams to this great river, belonging to the county, are the Camlet, the Vyrnyw, the Morda-Brook, the Perry, the Meole-Brook, the Rea, the Tern, the Bell-Brook, the Cund-Brook, the Worf, the Marbrook, and the Bore-Brook, all of them considerable waters. Those of most importance, which do not join the Severn, are the Morles, which falls into the Dee, the Teme, the Shelbrook, the Elf-Brook, the Weever, the Clun, the Ony, which discharges itself into the Teme, in Herefordshire, and the Corve; but besides these, there are nearly a hundred streams of minor extent, which our limits will not permit us to mention. The lakes here are numerous, but none of them are very extensive. That of Ellesmere, which is the largest, covers about 116 acres of ground.

*Minerals.*—Shropshire is well supplied with minerals. The mines of lead-ore, on the western side of the county, are extremely productive, and their product is reckoned to be of excellent quality. Copper and calamine are likewise found here in great quantities, but neither of them has hitherto been mined with any degree of success. Coal of a superior kind is wrought on the eastern side of the county, particularly in the parishes of Wellington, Lilleshall, Wrockwardine, Wombridge, Stirehley, Dawley, Little-Wenlock, Madeley, Barrow, Benthall, and Broseley. It is likewise found in the hundred of Stottesden, and to the southward of the Clee hills; also on the north and north-west confines of the county. Iron-stone, as is usually the case, accompanies the coal strata, as well as lime-stone, which is quarried in various places, but particularly at Lilleshall, Porth-y-Wain, and Llanymynach, and in the parishes of Cardiflon and Alberbury. This county further contains abundance of building-stone, and slates for covering roofs. At Pitchford, about seven miles S.E. from Shrewsbury, is a red sand-stone, approaching the surface in many places, which exudes a mineral pitch. From this rock is extracted an oil, known by the name of Betton's British oil. Mr. Arthur Aikin is preparing an interesting publication on the mineralogical stratification of this county.

*State of Property, &c.*—The extent of estates in this county is very various. While the possessions of a few noblemen and gentlemen include from 10,000 to 25,000 acres each, there is an infinite number of freeholders' and yeomen's estates of all inferior sizes. The number of freeholders entitled to vote amount to above 3000; and the total rental of the county, tithes inclusive, to about 900,000*l.* There is much copyhold tenure, but of easier customs than in most of the neighbouring counties. The lords of some customary manors have enfranchised the copyholders, upon receiving an equivalent in money; but the customs of the greater number are still preserved and acted upon. In the manors of Ford, Cundover, Wem, and Lop-

## SHROPSHIRE.

ington, the lands descend to the youngest son; and in the manors of Cardigan and Stretton, (where the eldest son succeeds,) in default of sons, the daughters are co-heiresses.

*Agriculture.*—The extent of farms is nearly as various as that of estates; but in general they are of a large size, and are, in some instances, held on leases for life; in others, for seven, ten, or twenty-one years; and, in many cases, from year to year only. The crops commonly cultivated are wheat, barley, oats, pease, turnips, and potatoes; hops, hemp, flax, and cabbages, are only raised in small quantities. The growth of hay and the improvement of pasture lands are rather neglected branches of Shropshire agriculture; but on the borders of the Severn, and in the vicinity of several of the lesser streams, there are many excellent tracts of meadow land, which produce grass in great luxuriance, without the aid of any other manure than what is deposited by the floods. The grasses most common in the county are the following: the sweet-scented vernal grass, Timothy grass, meadow fox-tail, and some species of the agrostis; but the latter flower too late to be of much use for cultivation. Several varieties of the poa and festuca are likewise common.

*Woods and Plantations.*—Notwithstanding large yearly falls of timber, there still remain in Shropshire some fine woods of oak, and a vast number of good hedge-row trees, chiefly ash and oak. Birches, both as trees and as fences, are common in the south-west district. There are besides, in this county, many large tracts of coppice-wood, and several extensive modern plantations; but the former suffer much by the demand for charcoal, which the numerous iron works in this and the adjoining counties occasion.

Of *waste lands*, Shropshire is comparatively free. Almost all the lands in cultivation are inclosed; and the commons are every day decreasing, so that few of any great extent remain, except that of Mors, near Bridgenorth, which measures five miles in length, and nearly three in breadth; and the high lands between Church-Stretton and Bishop's-Castle, and from Clun to the borders of Radnorshire, which are solely occupied as sheep-walks, and perhaps could not be better employed. There are several large mosses, and many smaller ones, in Shropshire. The chief district of moor-land is that in the vicinity of the village of Kinnerley.

*Roads and Canals.*—The turnpike-roads of this county are excellent; but the parish roads are in general bad, and the repair of them much neglected, from the want of proper surveyors. Canals, though late of introduction into Shropshire, are now frequent. The chief cuts are the Shropshire canal, which commences at Donnington wood, and terminates at Coal Port on the Severn, running through an extensive assemblage of coal and iron works; the Ketley canal, which joins that of the Shropshire; the Shrewsbury canal; and the Ellesmere Navigation, which forms in itself a system of canals, extending through that large and fertile tract of country which lies between the Severn on the south and the Mersey on the north, and between the confines of North Wales on the west and the borders of Staffordshire on the east, a space of 50 miles in length, and upwards of 20 in breadth, exclusive of the vallies which open into North Wales. Its grand object is to unite the Severn, the Dee, and the Mersey, and by that means open a communication between the district above mentioned and the ports of Liverpool and Bristol.

*Manufactures and Commerce.*—Among the manufactures of Shropshire, those of Ketley and other places in the iron district are the most considerable. Garden-pots, and other coarse earthen vessels, are made at Broseley, which is likewise

noted for the manufacture of excellent tobacco-pipes. At Caughley, in the same neighbourhood, is a china manufacture of great excellence, and at Coal Port is another of the same kind; besides one of that species of earthenware called the Queen's or Wedgewood ware. Shropshire also contains several mills for dyeing woollen cloths, and some cotton and linen manufactories. These various products of course form a considerable share in the commercial means of Shropshire, but its principal traffic is probably the staple trade of Shrewsbury, in flannels and Welsh webs, which are bought in large quantities at the markets of Pool and Oswestry, and are not only sent to every part of the kingdom, but are exported to different quarters of the world, particularly to the West Indies and to South America.

*Civil and Ecclesiastical Divisions and Government.*—Shropshire, like every other county in England, is governed by a lord lieutenant and custos rotulorum, a high sheriff, and a number of justices of the peace, besides the magistrates of the privileged towns. It is divided into fifteen hundreds, or districts, answering to that denomination; namely, Oswestry, Pimhill, North and South Bradford, Brimstrey, the liberty of Shrewsbury, the franchises of Wenlock, and the hundreds of Stottesden, Ford, Chirbury, Cundover, Manslow, Overs, Purflow, and the honour of Clun. These again are subdivided into 229 parishes, part of which are within the diocese of Litchfield and Coventry, and part within those of Hereford and St. Asaph.

*Parliamentary Representation and Chief Towns.*—Shropshire sends twelve members to parliament, two knights of the shire, and two burgesses for each of the boroughs of Shrewsbury, Ludlow, Bridgenorth, Wenlock, and Bishop's-Castle. The principal landed proprietors who have an influence in the representation, are the earl of Powis, the lord Bradford and Berwick, the Hills, the Corbets, and colonel Forester. The market-towns in the county are, Church-Stretton, Cleobury-Mortimer, Ellesmere, Hales-Owen, Madeley, Newport, Wem, Great-Wenlock, Oswestry, Whitchurch, and Wellington.

*Antiquities.*—Shropshire contains a great many objects of antiquarian interest. The chief Roman stations within its limits were Uriconium, now Wroxeter, Mediolanum, near Drayton, and Rutunium, near Wem. Antiquaries differ respecting the precise position of the two last, but with regard to the former, there is little doubt but it was a chief city of the Cornavii, founded and fortified by the Romans. Watling-street enters the county on the east, between Crackley-wood and Welton, and passes through it in a bending line to Leintwardine, in Herefordshire, on the southern borders. Of the Saxon period no ascertained remains exist; but of the Norman era, and of subsequent times, there are many; as the castles of Shrewsbury, Ludlow, Bridgenorth, Clun, and Red Castle, and the abbies of Shrewsbury, Haughmond, Buildwas, Wenlock, and Hales-Owen, several priories, and a great number of curious churches. The most remarkable encampments are those of Bury Ditches and the Walls, and at Purflow, Basford Gate, and Hawkstone. A General View of the Agriculture of Shropshire, by Joseph Plymley, M.A. Archdeacon of Salop, 8vo. 1803. Beauties of England and Wales, vol. xiii. by J. Nightingale and Ralph Rylance, 8vo. 1811.

SHROUD, from the Saxon *shroud*, a shelter, or cover, is used to denote the dress of the dead. This is required by statute to be made of sheep's wool only. See BURIAL.

If any one, in taking up a dead body, steals the shroud, the property of which remains in the executor, or the person who was at the charge of the funeral, it is felony.

SHROUDS, in *Sea Language*. See SHROUDES.

SHROVE-

**SHROVE-TIDE**, the time immediately before Lent ; thus called by our ancestors, because employed in *shriving*, that is, in confessing their sins to the priest, in order to a more devout keeping of the ensuing Lent fast.

Shrove-Tuesday is the day next before the first of Lent.

**SHROWDING** of *Trees*, the cutting or lopping off the top branches : this is only practised to trees that are not fit for timber, but designed for fuel, or some other present use.

Such trees the husbandmen find much preferable to coppice, as they need no fence to secure them ; because they stand in no danger from the browings and rubbings of cattle, which too have the benefit of grazing under them.

As for the time of shrowding, it is not to be practised till the trees have stood three or four years ; and then it must be done either at the beginning of the spring, or the end of autumn.

Those of the harder sort are not to be lopped above once in ten or twelve years, and that at any time in the winter. The pithy and soft woods are best shrowded in the spring. The stumps left should always be cut alope, and smooth, in order to call the water off, and prevent its sinking in, and rotting the tree.

**SHROWDS**, or **SHROUDS**, in *Sea Language*, are great ropes in a ship, which go up on both sides of all masts, except the bowsprit.

The shrouds are always divided into pairs, *i. e.* one piece of rope is doubled, and the two parts fastened together at a small distance from the middle, so as to leave a sort of noose or collar to fix upon the mast-head.

They are fastened below by chains to the ship's sides, and aloft, over the head of the mast ; their pennants, fore-tackle, and swifters, being first put under them : and they are served there, to prevent their galling the mast. The top-mast shrouds are fastened to the puttocks, by plates of iron, and by what they call *dead-men's eyes*, and laniers also, as the others are. See **PUTTOCKS**.

The shrouds, as well as the sails, are denominated from the mast to which they belong. Thus they are the main, fore, and mizen shrouds, the main-topmast, fore-topmast, or mizen-topmast shrouds, and main-top-gallant, fore-top-gallant, or mizen-top-gallant shrouds.

The number of shrouds by which a mast is sustained, as well as the size of the rope of which they are formed, is always in proportion to the size of the mast, and the weight of the sail it is intended to carry. The two fore-mast shrouds, on the starboard and larboard side of the ship, are always fitted first upon the mast-head ; and then the second on the starboard, and the second on the larboard, and so on till the whole number is fixed.

The intention of this arrangement is to brace the yards with greater facility, when the sails are close-hauled, which could not be performed without great difficulty, if the fore-mast shrouds were last fitted on the mast-head, because the angle which they would make with the mast would then be greatly increased. Falconer.

*Bowsprit* shrouds are those which support the bowsprit. *Bumkin* shrouds are those which support the bumkin. *Futtock* shrouds are those which connect the efforts of the top-mast shrouds with the lower shrouds. *Bentineck* shrouds are additional shrouds to support the masts in heavy gales. *Preventer* shrouds are similar to Bentineck shrouds, and are used in bad weather to ease the lower rigging.

The terms are, *ease the shrouds* ; that is, slacken them.

*Set taught the shrouds* ; that is, set them faster.

**SHROWD Trucks**. See **TRUCKS**.

**SHROWD Stoppers**. See **STOPPERS**.

**SHRUBS**, in *Botany* and *Vegetable Physiology*, are commonly understood to be plants with a perennial woody stem, of a more humble or slender form of growth than trees. Linnæus once attempted to define the limits between trees and shrubs, by the former having leaf-buds, the latter none ; but this distinction was soon found to be of no avail. Trees of hot countries have generally no buds, while many very humble shrubs of cold ones are furnished with this protection. This is so obvious, in Willows for example, that Linnæus probably only meant to apply the rule *generically*. Thus the whole genus of *Salix* having buds, and being mostly arboreous, every species of that genus, however diminutive, must be deemed a tree. Accordingly, *S. herbacea*, hardly an inch high, is termed in the *Flora Laponica*, the least of all trees. But the shrubby genus *Lonicera* has still more elaborate buds than *Salix*.

**SHRUB**, in *Gardening*, a low woody plant of branchy growth and ornamental appearance ; it is sometimes, however, of a large growth and stature. Shrubs are commonly divided into the evergreen and deciduous kinds ; and they may be subdivided still farther into the exotic or tender and the hardy sorts, as well as into such as are rarely seen or met with, and such as are well known and in common cultivation. In the former as well as latter of these great divisions, the plants may likewise be separated and arranged according to their sizes, forms, modes of growth, colours, and other particulars : in the last of which, it has been observed, there is every shade between the ruscus, which is among the least, and the Bermudian jumper, which is nearly the largest ;—from the holly, which is slightly tinged with red, to the box, which is of a golden yellow :—in shape, from the cypress, which grows in the form of a spire, to the daphne tarton raira, which forms a globular tuft upon the surface of the ground ;—from the hederæ, which fastens itself to the wall, to the andromeda and viçæ, which recline themselves upon the surface.

In the latter, the plants are said to be diversified in each of these particulars, being capable of division, as they may be cultivated principally for the beauty of their flowers, as the rhododendron, erica, and many others ;—for the smell, as the sweet briar, abanthoides, cleriodendron, jasminum, and some others ;—for both these qualities, as the rose, Cape jasmine, and a few more :—or as being grown, in a great measure, for the beauty of the leaves, as the acuba, variegated holly, elder, and some others ;—for the purpose and appearance of the fruit, as the mespilus pyracantha and the orange ;—for the beauty of the whole plant, as the aristotelia, and several others ;—and, lastly, the greatest proportion for all these properties together, as the myrtle, laurustinus, laurel, and some others. Some of these, however, belong to the former of the above general divisions or classes.

Shrubs are of very great importance in forming all sorts of collections in gardens, and other places ; and in ornamental pleasure-ground works they constitute a class of materials of the most interesting kind, which cannot be done without.

In such situations and works they are arranged, varied, and placed out, in many different ways, so as to produce the most pleasing effect and variety in the particular intentions with which they are planted or set out. See **SURCUBERRY**.

It has been observed by Mr. Loudon, in his work on "Ornamental Gardening," that the evergreen class of shrubs are deficient in most situations, as well as trees of the same sort ; but that they deserve to be very generally planted, equally on account of their uncommon beauty in the

the winter season, as for their contrast with the yellow and russet tints of the deciduous kind, and trees of the same nature, in the autumnal and spring seasons. They ought, generally, according to him, to be the prevailing sorts planted near the houses and buildings of country-seats, not only for the reasons suggested above, but because they are capable of concealing some part or parts of the edifices, disguising their real extents, and thus blending them at all seasons with the surrounding scenery. There is also another circumstance in their favour, which is the superiority of their shelter and shade.

It is thought, also, that the cypress is too seldom planted in such situations, as it has the capability and power of giving a rich classical appearance and effect to them; as is seen in some cases, as at Foxley and Yoxal Lodge.

And the holly, it is suggested, should be planted still more than any other shrub, in particular cases; as no other is capable of affording and producing such an excellent and diversified effect in woody scenery, as is exemplified in some forest situations.

The ivy is capable, it is said, of answering three important uses, and of course deserving of more frequent growth. These are the varying of the stems of single trees, and small groups of them; the giving of effect to old decaying trees, and the rendering of ugly trees interesting, as well as other similar rural purposes; the producing of variety in different sorts of buildings; and the giving of ornament and utility to works of the country kind.

In the first of these intentions, in different cases, where the number of trees of the same kind are considerable, and very much alike, which are in the fore-ground, one or several of them may be varied and diversified by the ivy shrub, in probably as happy a manner, and with as good an effect, as in any other way, and better than by the use of any sort of deciduous climbing plant. Single trees can always be rendered interestingly different by these means, as well as old and ugly trees of different sorts.

In the second use, where cottages, ruins, irregularly formed buildings, old houses, and other similar structures, are to be varied, partially concealed, and rendered different in their external appearance, but which cannot be cheaply enough done in other ways, they may be highly and richly diversified and decorated by the simple planting of the ivy shrub, and directing it so as to cover in different places or parts. The expence of such works would also be less, in many instances, it is remarked, if the external appearance of them were contrived so as to admit this plant; which would not only vary and alter them generally, but might occasionally be substituted for, and supply the place of, particular parts, as is exemplified in many instances.

The last of these intentions is that of planting the ivy shrub against walls of the stone kind, dikes, and sunk fences between fields, and other similar purposes, in the view of rendering them more ornamental and durable. The chequering of them in this way, on their sides, with shades of green, and little ribs or columns, and richly mantling their tops, have, it is said, much effect in producing variety, and at the same time in rendering them more lasting. Mortared and unmortared walls are likewise preserved and secured by it. This creeping shrubby plant may consequently be of extensive utility in various ways; as, besides affording beauty, shelter, and durability, it may be beneficial in thickening hedges in the vicinity of the sea-coast, when joined with the elder. It should, in all cases, be carefully planted, either by sets or young seedlings, which last is by much the readiest mode of raising and providing it. Nothing more is wanting, as it succeeds well in most soils,

situations, and exposures. Where tall plants are wanted for particular uses, they must be provided with good roots.

In the deciduous kind of shrubs, the modes of varying and planting are very different, according to their nature, habits, sizes, and other qualities and circumstances. For the most part, however, the larger sorts are put more out of the way, in order that the smaller and more curious kinds may be more fully exposed to view. The peculiar properties in some of this description of shrubs also direct the modes and manners of planting them, as that of the time of flowering, and several others. They are varied and planted differently, likewise, for a great variety of other different reasons.

In planting the laburnum, as there are two sorts, which differ greatly in their spray or small twigs and foliage, that with the smaller and more delicate branches and flowers should constantly be chosen for putting out with other shrubs; the other, which is of much larger growth, is well suited for poor gravelly soils, rocky banks, and the rocky margins of water, where, in the two latter situations, the plants may sometimes be seen in great perfection.

Shrubs of these different kinds are raised and produced in many different ways, as may be seen under their different particular proper heads.

Some sorts of shrubs, particularly in the early state of their growth, stand in need of not merely a soil and situation, but a mode of cultivation which is adapted to their different natures and habits. And though most shrubs require to have the earth or soil about them either frequently stirred, or kept clean and free from all plants of the weed kind, there are some that succeed best when the surface of the ground is overrun with low plants of the moss kind.

In all cases, shrubs are to be preserved in a neat and perfect order, by the removal of the decayed and withered parts, and the proper cutting in of particular shoots and branches where necessary, especially in some of the deciduous kinds. In the evergreen class, the knife or shears, however, are very seldom to be applied, except for the removal of the destroyed parts, which are constantly to be carefully taken away.

**SHRUB, Fruit**, that sort of low shrubby plant which bears fruit of some kind or other. Shrubs of this kind are mostly very useful, and not few in number. The sorts are various, as the gooseberry, the currant, the raspberry, and some others, cultivated in garden situations; and the berry or barberry, and a few other kinds, in those of the shrubbery. Shrubs of this description, in most cases, require careful attention in cutting, managing, and keeping the ground in proper order, by due cultivation, and the proper use of suitable manure. See *SMALL Fruits*, and *STANDARD Fruit Trees*.

In planting them, those of the garden sort are most properly and usefully put out in situations by themselves, and not in the usual mode, on the sides or borders of the different cultivated compartments of the garden ground.

Those which produce ornament, as well as fruit, are to be placed out in variety with other shrubs, in the more open parts of shrubberies, or alone in particular cases.

**SHRUBS, Stealing of.** See *LARCENY*.

Wilfully spoiling or destroying them is a species of that malicious mischief, which subjects the offender to pecuniary penalties for the first two offences, and for the third, if it be committed in the day-time, and even be the first at night, to the guilt of felony, and transportation for seven years. 6 Geo. III. cap. 36. and 48.

**SHRUBBERY**, in *Gardening*, a tract, portion, or space of ground, which is planted with shrubs, trees, and flower plants,

## SHRUBBERY.

plants, for the purpose of ornament. The term is, however, perhaps the most properly applied to narrow belts and strips of ground, planted with shrubs and flowers, which are sometimes the principal ornaments of small seats, and other similar constructions and conveniencies. They are contrived in different forms and modes, for the purpose of giving the desired effect; and the notion of such schemes of planting shrubs and flowers is considered by Mr. Loudon as good and proper, as when executed according to the principles of nature and good taste, they must produce effects of the interesting as well as the pleasing kind; but that from the reverse having been so frequently the case, their tawdry insipidity has been justly reprobated by some, as Mr. Knight, in the following line, &c.

“Curse on the shrubbery’s inspid scenes.”

It is supposed that shrubberies are, in general, made and contrived with the intention of procuring walks, which may either conduct or direct to some particular place or scene, such as the kitchen garden, the farm, a wood, or any other similar object; or they may lead and extend merely through the shrubberies, for their own sakes, and such views of external objects as can be produced from them, or as are deserving of attention. In designing and forming shrubberies, therefore, keeping the above in view, these three points will, it is thought, require to be particularly attended to: first, the arrangement, distribution, and grouping of the shrubs, which ought to be that of general nature; in the second, the intermixing of the glades and pastures, which, in most cases, is an essentially requisite consideration; and in the third or last, the judicious introduction of the views of the more distant scenery, which is generally desirable, unless in such parts as, by way of utility or contrast, are preserved in a state of umbrosity.

The two latter requisites are, it is said, naturally connected with picturesque improvements, the general principles of which are blended and intermixed with this branch of ornamental gardening.

The directions which this able designer of rural works of this nature has given for the forming of shrubberies with proper taste, in different cases, situations, and circumstances, are, that when such groups of shrubs and flower plants are small and placed upon lawns, they should always be of very irregular shapes; but that, when upon gravel, their forms must depend upon circumstances. In cases where they are in a part in which art is avowed and ought to prevail, then the more artificial the forms are, so much the better; but that if merely a group for separating, dividing, or varying a road, walk, or natural path at a distance from artificial scenes, then the shape should be as irregular as in those upon lawns. Whether such shrubby groups are made in a regular or irregular manner, they almost in every case require to be cultivated or wrought over for some years afterwards. This, in the mode of digging and working them which has been usually had recourse to, produces, it is said, a harsh and disagreeable boundary line; which, in addition to the means of proper arrangement, suitable grouping, and the natural connection of surface, may be improved principally, it is supposed, by the destruction of such lines of separation in as complete a manner, as high a degree, and as extensively as possible. Nothing, it is thought, can be more readily or more easily accomplished, as it is only requisite to keep the earth on the margins or borders of such groups of the same level as the surfaces of the lawns or pastures, and to suffer both to unite and blend harmoniously together, or with each other. And as all groups of this shrubby kind are only dug or wrought over during a certain period of

time, as until the shrubs become so large as to render further culture unnecessary; the pasture should be allowed to gradually encroach and spread itself among the shrubs and flower plants, until at last it wholly covers the surface. After this, the shrubby group becomes rough and picturesque; the flower plants, still continuing to grow among the shrubs, will, it is supposed, be productive of exactly what is seen to happen in natural groups; with this elegant difference, that in place of nettles, thistles, and such coarse gross weeds, which however, it is remarked, are as good to the painter as the finest flower plants, there will be had the narcissus, saxifrage, saponaria, and others, which are quite in character with the rest of the pleasure-ground, and thrive well among pasture. It is suggested, that in planting the shrubs in such groups, the great art consists in putting them in irregularly; for though the outline of the ground to be cultivated must, even under the best taste, be somewhat formal, yet the shrubs can always be planted as irregularly as if no outline or form of group existed. This is, however, said to be a plan or manner of distribution, which has never been put in practice; as whatever the form of the ground may be which is to be dug and planted, the shrubs are distributed in a regular manner over every part of it:—even when digging is no longer attended to, still none of the shrubs are thinned out, but the whole left a formal unconnected clump of vegetation, an appearance, it is observed, as different from the irregular group-thickets of nature, as a green hillock is from a rocky precipice. It is stated, however, that the groups of this nature, or rather those masses of formal shapes which are placed in particular situations, such as ovals in the fronts of small villas, or basket-work patches upon the lawns in the fronts of residences of the mansion kind, should always have determinate outlines; as being devoted, in a great measure, to tender flower plants and flowering shrubs, they will require to be constantly in a cultivated state. Their outlines or boundaries may, it is supposed, be properly formed, according to circumstances, either of elegant masonry, wood, basket-work, or of plants of the slower kind, such as thurst, the daisy, and some others, and not infrequently, when surrounded by gravel, by a broad margin of turf. In regard to the general forms of such shrubby planted masses, it is said that they may be oval, circular, pentagonal, or fanciful, according to pleasure; and that their surfaces may either be kept level with the lawns or other parts, or be gradually raised from their margins to their centres. It is however noticed, that when raised in this way, the sides should always be made to present a concave slope, and not that of a convex one, as is most commonly the case, and which has a very bad effect in different instances, as in the public squares of the metropolis, &c. Basket-work shrubby groups have not unfrequently, it is remarked, a very pretty effect when covered with moss. Others which are unconnected among themselves, and which have shapes that are rather unsuitable to the nature of the situations in which they are formed, are likewise productive of variety. In all cases, some sort of agreeable effect ought to be afforded in as striking a manner as possible.

It is conclusively remarked, that though the connection of surface in such shrubby groups is always of importance, neither those of the irregular or regular shapes ought ever to be placed in any situation, except where they have a proper relation and union with what surrounds them.

In the larger and more extensive works of the shrubby kind, the same rules and principles will be necessary to be had recourse to, but with a greater attention to the production of variety and effect. These are to be accomplished by

fuch means as have been already suggested, and by giving them a more natural conformity, as well as by the introduction of greater diversity in the shrubs, trees, and other sorts of plants that are made use of in the formation of them. It is indeed observed, that one of the most effectual means of rendering rural scenes still more interesting than they commonly are, is by introducing a more extensive variety of shrubs than is usually employed, a vast number of which are capable of answering the purpose. They are not, however, to be planted in such situations in the common indiscriminate manner, but with much regard to the effect which they are to produce. In short, it is concluded, that it is in the shrubby, or those parts of pleasure-grounds which contain flower plants, shrubs, and trees,—which occupy considerable space,—exhibit views of the country or of other parts of the ground, that ornamental gardening and picturesque improvement blend themselves together in producing those happy effects which so much interest the feelings and fancy.

**SHRUBBY-Horok-Weed**, in *Agriculture*, a plant of the shrubby weed kind, which is often troublesome and injurious in woods and plantations. See **HIERACIUM**, and **WEEDS**.

**SHRULE**, in *Geography*, a river of the county of Tyrone, Ireland, which joins the Moyle near New Town Stewart. There are also several parishes of this name in Ireland, but none called from a town now existing, except Shrule in the county of Mayo, on the borders of the county of Galway; 106 miles N. by W. from Dublin.

**SHTUKA**, a powerful tribe or kabyle in the province of Sufe, in the southern division of the empire of Morocco, inhabited by Shelluks, amounting in number to 380,000.

**SHUARIF**, a small low island in the Red sea, near the coast of Africa. N. lat. 24° 22'.

**SHUBENACADIE**, a river of Nova Scotia, which rises within a mile of the town of Dartmouth, on the E. side of Halifax harbour, and discharges itself into Cobscook bay, receiving in its course the Slewinnck and Gays rivers. The large lake of the same name lies on the E. side of the land that leads from Halifax to Windsor, and about 7 miles from it, and 121 from Halifax.

**SHUCK**, in *Agriculture*, provincially a stouk, or twelve sheaves of corn set up together in the harvest field.

**SHUD**, in *Rural Economy*, a word sometimes provincially used to signify shed.

**SHUG**, in *Agriculture*, a term used to imply the shaking of any thing, as hay, &c.

**SHUGGINGS**, a word signifying that which is shed or scattered, as grain at harvest, &c.

**SHUHUSHU**, in *Geography*, a village of the pachalic of Bagdad, one day's sail from Korna, and situated on the bank of the Euphrates. It is as large as Samavat (which see), but much more flourishing; for the Euphrates, which is navigable, even in the driest season, for boats of considerable burthen as far up as this place (where the effects of the tide are also felt), enables the inhabitants to carry on a trifling traffic with Bassora. Shuhushu is a great mart for horses, and is famed for the richness of the cloves raised in its vicinity.

**SHUK**, in *Agriculture*, a term sometimes provincially applied to a husk or shell.

**SHUKERA**, in *Geography*, a town of Thibet; 42 miles S. of Gangotre.

**SHULA**, or **SHULI**, in *Mythology*. See **SULA**.

**SHUMAN**, in *Geography*, a town of Grand Bucharia; 30 miles W. of Vahgherd.

**SHUMBERG**, a town of Iltria; 5 miles N.N.E. of Pedena.

**SHUME**, or **ASSHUME**, a violent hot wind of Africa, or, as they are called, **Oncas**, which, in the intermediate journeys between several parts of the Desert or Sahara, occasions great inconvenience and distress to travellers. It sometimes wholly exhales the water carried in skins by the camels for the use of the passengers and drivers: on which occasions the Arabs and people of Soudan affirm, that 500 dollars have been given for a draught of water, and that 10 or 20 are commonly given, when a partial exhalation has occurred. In 1805, a caravan proceeding from Tombuctoo to Taflet was disappointed in not finding water at one of the usual watering-places, when, as it is said, all the persons belonging to it, 2000 in number, besides 1800 camels, perished by thirst. The intense heat of the sun, aided by the vehement and parching wind that drives the loose sand along the boundless plains, gives to the Desert the appearance of a sea, the drifting sands resembling exactly the waves of the sea, and hence aptly denominated by the Arabs "el Bahar billa maa," a sea without water. During the prevalence of this wind, it is impossible to live in the upper rooms of the houses; so that the inhabitants retire to subterraneous apartments, cellars, or warehouses on the ground-floor, eating only fruits, as the water-melon or prickly pear, as the animal food at this time is loathsome whilst hot, and has scarcely time to cool before it becomes tainted. The walls of the bed-chambers, being of stone, are moistened by throwing upon them buckets of water, in order to render the rooms habitable towards the night; and so great is their heat, that in doing this, the effect is similar to that which is produced by casting water on hot iron. Mr. Jackson says that he has felt the hume 20 leagues out at sea. When in N. lat. 30°. W. long. 11° 30', a quantity of sand fell on the deck. He adds, that he never found any extreme inconvenience from the hume N. of the province of Sufe, although at Mogodor it is sometimes felt, but not so severely, during three days.

The Akkaababs, or accumulated caravans, which cross the great desert of Sahara, and consist of several hundred loaded camels, accompanied by the Arabs who let them to the merchants for transporting their merchandize to Fez, Morocco, &c. are sometimes obliged suddenly to strike their tents, and proceed on their journey, when the hume rises and drifts the loose sand along the plains, which attaches to every fixed object in its course, and soon buries it. We shall here add, that the guides of these accumulated caravans, being enabled by the two pointers to ascertain the polar star, steer their course with considerable precision, and that they often prefer travelling in the night to enduring the suffocating heat of the scorching meridian sun. When the Akkaabah reaches Akka, the first station on this side of the Desert, and situated on its confines, in Lower Sufe, which is a part of Biledulgerid, the camels and guides are discharged, and others are there hired to proceed to Fez, Morocco, Terodant, Taflet, and other places. The Akkaababs perform the traverse of the Desert, including their sojournments at El-wahs, or Oafes, in about 130 days. Proceeding from the city of Fez, they go at the rate of 3½ miles an hour, and travel seven hours a day: they reach Wedinoo, Tatta, or Akka, in 18 days, where they remain a month, as a grand accumulated Akkaabah proceeds from the latter place. In going from Akka to Tagassa, they employ 16 days, sojourning here 15 days more to replenish their camels; they then proceed to the Oasis and well of Taudeny, which they reach in seven days, and after staying there 15 days, they proceed to Tombuctoo, which they reach the sixth day, making a journey of 54 days actual travelling, and of 75 days' repose; being altogether, from Fez

Fez to Tombuctoo, 129 days, or 4 lunar months and 9 days. See **TOMBUCTOO** and **WEDINOON**. See also **CARAVAN**.

**SHUMSHABAD**, in *Geography*, a town of Hindoostan, in Lahore; 6 miles S.E. of Attock.

**SHUMUM**, a town of Egypt, on the Nile; 13 miles N.W. of Cairo.

**SHUNAITE' EZZAILE**, a town of Egypt; 30 miles S.W. of Girgê.

**SHUNAR**, a town of Hindoostan, in Bahar; 22 miles N.E. of Bahar.

**SHUPARE**, a town of Candahar; 45 miles N. of Attock.

**SHURBA**, a town of Asiatic Turkey, in Natolia; 30 miles E.S.E. of Boli.

**SHURDHUR**, a town of Hindoostan, in Guzerat; 50 miles E.N.E. of Junagur.

**SHUREGIAN**, a town of Persia, in the province of Kerman; 95 miles S.E. of Sirgian.

**SHUREJAN**, a district of Grand Bucharia, in the W. part of the kingdom of Balk.

**SHURFFAH**, a town of Algiers, near the coast; 6 miles E. of Dellys.

**SHURMEEN**, a town of Syria; 32 miles S.S.W. of Aleppo.

**SHURMIN**, a town of Persia, in the province of Khorassan; 25 miles N. of Maru-errud.

**SHURPH el Graab**, i. e. *the pinnacle of the ravens*, a rugged mountain of Algiers; 25 miles N. of Tremecen.

**SHURUBUI**, a town of Brazil, in the government of Para; 22 miles E. of Pauxis.

**SHUS**, the name of famous ruins in the Persian empire, situated in the province of Kuzistan, or Chufistan, (the ancient *Sufiana*, which see,) about seven or eight miles to the west of Dezphoul, a town which lies on the eastern banks of the Abzal, in a beautiful and spacious plain, 28 miles W. of Shuster, and celebrated for its elegant bridge of 22 arches, 450 paces in length, 20 in breadth, and about 40 in height, the piers of which are constructed of large stones, and the arches and upper parts of burnt brick. The ruins of Shus extend about twelve miles from one extremity to the other, stretching as far as the eastern bank of the Kerah, occupying an immense space between that river and the Abzal, and, like the ruins of Ctesiphon, Babylon, and Kufa, consisting of hillocks of earth and rubbish, covered with broken pieces of brick and coloured tile. The largest and most remarkable of these mounds stand at the distance of about two miles from the Kerah. The first is, at the lowest computation, a mile in circumference, and nearly 100 feet in height; and the other, although not quite so high, is double the circuit of the former. These mounds bear some resemblance to the pyramids of Babylon, with this difference, that instead of being made entirely of brick, they are formed of clay and pieces of tile, with irregular layers of brick and mortar, five or six feet thick, to serve, as it should seem, as a kind of prop to the mass. Large blocks of marble, bearing hieroglyphics, are not unfrequently discovered here by the Arabs, when digging in search of hidden treasure; and at the foot of the most elevated of the pyramids stands the "tomb of Daniel," a small, and apparently a modern building, erected on the spot where the relics of that prophet are believed to rest.

These ruins, according to major Rennell, represent the celebrated city of Sufa; but another distinguished oriental geographer controverts this opinion, and maintains that Shuster, and not Shus, occupies the situation of the ancient metropolis of the East. The arguments alleged by major

Rennell in favour of his opinion are, 1st, the similarity of name, and the situation, which agrees better with the distance between Sardis and Sula, mentioned in the tablets of Aristagoras, than that of Shuster; 2dly, the legend of the prophet Daniel, whose coffin was found at Shus; and 3dly, that Sufa ought to be placed on a river, which has its source in Media. Dr. Vincent, in reply, says, that the similarity of name is a corroborating circumstance, when we are sure of our position. But till the position be ascertained, it is only a presumptive proof, and often fallacious; and that Shuster approaches still nearer than Shus to Shushan, which is its title in Scripture, and Shushan differs not from Sufa, but by the insertion of a dot in the letter *Shin*. To the legendary tradition of the tomb of Daniel, little more respect is due, as the learned doctor conceives, than to the legends of the church of Rome and the Mahomedan traditions. Sufa, he adds, was on the river Euleus; Shuster is more ancient than Shus; Sufiana, the name of the province, approaches nearer to Shushan; and Kuzistan, its modern appellation, derived from the mountains which surround it, is evidently connected with the Kisi, Kushi, and Koffi of the Greeks. Nearchus failed up to Sufa, without entering the Shat-ul-Arab, which he would not have done, if that city had stood on the Kerah; and when Alexander descended the Euleus, he sent his disabled ships through the cut of the Hafar, into the Shat-ul-Arab; and, finally, a strong reason for placing Sufa at Shuster occurs in Ebn Haukul, who says, that there is not in all Kuzistan any mountain, except at Shuler, Jondi Shapour, and Ardz; and as the cattle of Sufa is represented by historians as a strong place, it is reasonable to suppose that it stood upon a hill. Mr. Kinneir, in his "Geographical Memoir on the Persian Empire," has examined with critical skill and great candour the objections of Dr. Vincent, and the principles on which they are founded; and the result is, that he inclines to favour the opinion of major Rennell, in support of which he cites the authority of Strabo, who says, that the Persian capital was entirely built of brick, there not being a stone in the province; whereas the quarries of Shuster are very celebrated, and almost the whole of the town is built of stone, but there is no such thing in the environs of Shus, which was anciently formed of brick, as appears from our author's description of the pyramids that still remain. However the question concerning the site of the city of Shus be determined, it is now a gloomy wilderness, infested by lions, hyænas, and other beasts of prey.

**SHUSJIMIAN**, a town of Persia, in Khorassan; 6 miles N. of Maru.

**SHUSTER**, a province or district of the Persian empire, constituting one division of Kuzistan, or Chufistan, the other being formed by the territories of the Chab Sheikh. The latter extend from the banks of the Tab to the conflux of the Karoon and Abzal, and from the shore of the Persian gulf to a range of hills which skirt the valley of Ram Hormuz to the south. The most fertile spots in this district are those in the environs of Dorak, the capital of the Chab prince, and on the banks of the Hafar and Shat-ul-Arab. Here dates and rice are produced; and hence the Sheikh Mahomed derives his principal revenues. The wheat and barley that are grown are scarcely sufficient for the supply of the inhabitants. The rice harvest is in August and September, and that of other grain in April and May. The northern and western parts of the country afford tolerable pasturage; and here the wandering tribes, which compose the principal part of the population, pitch their tents. Both banks of the Karoon, from its junction with the Abzal, eight furlongs below Shuster, to the ruins of

Sabla, are uninhabited, and consequently almost wholly uncultivated, and covered with brush-wood, the resort of lions, wild bears, and other animals. Morasses are common. The Chab country is watered by three rivers, *viz.* 1st, the Karoon, supposed by some geographers to be the ancient Choaspes, but Kinneir disputes their identity; it rises 22 furlongs S.W. of Ispahan, and after receiving many tributary streams in the mountains of Lauristan, flows through the city of Shuster to the village of Bundekeel, eight furlongs to the S. of that city, where it meets the Abzal: pursuing thence a southerly course, as far as Sabla, N. lat.  $30^{\circ} 32'$ , and 30 miles E. of Bassora, it divides itself into two branches, one of which discharges itself into the sea at Goban, and the other, assuming the name of Hafar, separates, after a course of 14 miles, into two branches, one of which passes through an artificial canal, three miles in length, into the Shat-ul-Arab, and the other enters the sea by the name of the Bamishire. 2dly. The *Tab*, which see; and the 3d is the Jerahi, or ancient Pasitigris, which descends from the mountains behind Bebahan, in the province of Fars, and passing within a few miles of the walls of that city, runs through the vale of Ram Hormuz to old Dorak, in the territory of the Chab Sheikh. Here it is dispersed in various directions for the purpose of agriculture; and the water afterwards is lost, or occasions the vast morasses in the vicinity of modern Dorak. The principal towns in the district of Chab Sheikh are, Dorak or Felahi, Ahwaz, Endian, Mashoor, Goban, and Jerahi, whence the river, so called, derives its name. The revenues of the Chab Sheikh amount to five lacs of piastres, or about 50,000*l.* sterling a-year; and he can bring into the field 5000 horse, and 20,000 foot.

The territories attached to the government of Shuster constitute the fairest portion of Susiana. It derives its fertility from four noble rivers, and from a multitude of smaller streams. This wealthy province, which, according to Strabo, yielded to the husbandman 100 or even 200 fold, and was rich in its productions of cotton, sugar, rice, and grain, is now, for the greatest part, a forsaken waste. The only indications to the contrary occur between Bundekeel, Dezphoul, the vicinity of Haweeza, and the vale of Ram Hormuz. From the Abzal to the Tigris, and the river Gyndes, on the western side, and from the banks of the Karoon to those of the Shat-ul-Arab, all is dreary and desolate; and on the E. side of Shuster a lonely wild, upwards of 60 miles in length, extends from that city to the entrance of the valley of Ram Hormuz. Although the inhabitants of the towns and villages groan under the arbitrary sway of the governor of Shuster, his authority is hardly acknowledged by the wandering tribes, both Persian and Arabian, of Kuzistan. Of the four great rivers which embellish and fertilize the district of Shuster, Karoon deserves the first mention. Next in magnitude is the Abzal, which has two sources, one in the Shatur Koh, near Boorjird, and the other in the mountains of Lauristan: these form a junction N. of Dezphoul, and after passing under the walls of that city, empty themselves, after a winding course, into the Karoon, at Bundekeel. The third river is the Kerah, or Haweeza river, called by the Turks the Karafu, which is formed by the junction of many streams in the province of Ardelan, in Kurdistan: it runs through the plain of Kermanshaw, meeting the Kazawur and the Gamafu. The Karafu, increased in magnitude by tributary streams, flows with a furious course towards Kuzistan, and supplied with an accession of water, it passes on the W. of the ruins of Shus to the city of Haweeza, and enters the Shat-ul-Arab, about twenty miles below Korna. The

fourth river is that supposed by Mr. Kinneir to be the ancient Gyndes, which proceeds from an unknown source in the mountains of Lauristan, and joins the Tigris between Koot and Korna.

Shuster, the capital of Kuzistan, and the residence of a Beglerbeg, is situated in N. lat  $32^{\circ}$ . E. long.  $48^{\circ} 59'$ , at the foot of the mountains of Bucktiari, on an eminence commanding the rapid course of the Karoon, across which is a bridge of one arch, upwards of eighty feet high, from the summit of which the Persians often throw themselves into the water, without the slightest injury. On the western side it is defended by the river, and on the other side by the old stone wall, now fallen into decay. The houses are good, being principally built of stone, but the streets are narrow and dirty. The population, consisting of Persians and Arabians, exceeds 15,000 souls; and it has a considerable manufacture of woollen stuffs, which are exported to Bassora, in return for the Indian commodities brought from thence. This city is generally believed to be the ancient Sufa; but some approved geographers entertain a different opinion. (See SHUS.) Shus, in the old Persian language, means pleasing, or delightful, and Shuster still more delightful; and the name is said to be given to this city by Sapor, the son of Artaxerxes Babegan, by whom it was founded, and caused to be built under the inspection of his prisoner, the Roman emperor Valerian. It was once, without question, a place of vast extent, and no inconsiderable magnitude. The castle, dyke, and bridge, are most worthy of notice. The castle occupies a small hill at the western extremity of the town, commanding a fine view of the river, mountains, and adjoining country. This fortress is, on two sides, defended by a ditch, now almost choked up with sand, and on the other two sides by a branch of the Karoon. It has one gate-way, formerly entered by a draw-bridge. The hill is almost entirely excavated, and formed into furdahs and subterraneous aqueducts, through which the water still continues to flow. Near the castle is the dyke, or "bund," built by Sapor across the Karoon, with a view of turning a large proportion of the water into a channel more favourable for agriculture, than that which nature had assigned it. This dyke is constructed of cut stone, bound together by clamps of iron, about 20 feet broad, and 400 yards long, with two small arches in the middle. It has lately been rebuilt by Mahomet Ali Meerza, governor of Kermanshaw, and its beneficial effects are already experienced. The artificial canal, occasioned by the construction of this dyke, disembogues, after a long winding course, into the Dezphoul, half a mile from Bundekeel. Near the canal is a bridge, built of hewn stone, consisting of 32 arches, 28 of which are yet entire. The city of Shuster is so remarkable for its salubrity, as to be the continual resort of invalids from the surrounding territories. In summer the heats are excessive from nine in the morning to the same hour at night, when the air is refreshed by a gentle breeze from the N.W. During the day the inhabitants take refuge in subterraneous chambers, and pass the night on the flat roofs of their houses. The winters are mild, and the springs temperate and delightful. Shuster affords excellent springs. Kinneir's Geog. Mem. of the Persian Empire.

SHUT in Land. See LAND.

SHUTESBURY, in *Geography*, a township of America, in Hampshire county, Massachusetts, on the E. side of Connecticut river; 90 miles W. by N. from Boston, containing 939 inhabitants.

SHUTTING, in *Anchor-Making*, denotes joining or welding one piece of iron to another.

**SHUTTING-UP**, in *Rural Economy*, a term applied to woods and plantations, which signifies the inclosing and securing them from the injuries which are done to them by neat cattle and other sorts of live-stock getting into them, and the keeping of them secure and safe for a certain period of time before they are cut over and converted to use in their different intentions. See **WOOD**.

It also implies the removing of live-stock from the pastures and other grafs lands, for the purpose of closing them in the view of having the former of a more full, suitable, and better growth or bite, as it is called, and the latter more productive of grafs for hay. See **MEADOW**, and **PASTURE**.

**SHUTTLE**, in the *Manufactures*, an instrument used by the weavers, which, with a thread it contains, either of woollen, silk, flax, or other matter, serves to form the woofs of stuffs, cloths, linen, ribbands, &c. by throwing the shuttle alternately from left to right, and from right to left, across between the threads of the warp, which are stretched out lengthways on the loom.

In the middle of the shuttle is a kind of cavity, called the *eye* or *chamber* of the shuttle; in which is inclosed the spool, which is a part of the thread destined for the woof; and this is wound on a little tube of paper, rush, or other matter.

The ribband-weaver's shuttle is very different from that of most other weavers, though it serves for the same purpose: it is of box, six or seven inches long, one broad, and as much deep; shod with iron at both ends, which terminate in points, and are a little crooked, the one towards the right, and the other towards the left, representing the figure of an  $\infty$  horizontally placed.

**SHUTTLE**, in *Inland Navigation*, a term expressing a small sluice, paddle, &c.

**SHUTTLEWORTH**, **OBADIAH**, in *Biography*, organist of St. Michael's church, Cornhill, was elected, on the resignation of Harte, for St. Dione's Back-church, who was succeeded by Burney in 1749. Shuttleworth, soon after his election at St. Michael's, was appointed one of the organists of the Temple church. He was the son of Shuttleworth of Spitalfields, the father of a remarkable musical family, and had acquired a small fortune by teaching the harpsichord, and transcribing the compositions of Corelli, before they were printed in England. He had three sons and a daughter, all good musicians; and had frequent concerts at his house for the amusement of his friends, in which the sons played the violin and tenor, the daughter the harpsichord, and the old gentleman the viol da gamba. His son Obadiah, particularly, was so admired a performer on the violin, as to be ranked among the first masters of his time. He led the band at the Swan concert, from its first institution to the time of his death, about the year 1735, when he was succeeded by Felting. His brothers were excellent performers on the violin, and employed in all the city concerts. But Obadiah is almost a single instance of the same musician being equally admired for his performance on two different instruments. He was such a favourite player on the Temple organ, that great crowds went thither to hear him of a Sunday evening, when, after service, he frequently played near an hour, giving a movement to each of the solo stops previous to his final fugue on the full organ.

**SHWAN-PAN**, the name of a Chinese instrument, composed of a number of wires, with beads upon them, which they move backwards and forwards, and which serves to assist them in their computations. See **ABACUS**.

**SHWAYEDONG**, in *Geography*, a small but neat town of the Birman empire, on the Irawaddy, containing about

300 houses, ranged in a regular street; each dwelling having a small garden, fenced with a bamboo railing. Its two monasteries and a few small temples did not engage the particular notice of Col. Symes and his companions; but the tall and wide-spreading trees that overshadowed them were objects of pleasing contemplation. Symes's *Embassy to Ava*, vol. ii. p. 254.

**SHY**, in *Agriculture*, a provincial term, signifying high-mettled or head-strong, in the manner of wild colts, &c.

**SHYAMULA**, in *Mythology*, a name of Parvati, the consort of the Hindoo deity Siva. It means with a blue body; and is, with many other names of similar derivation, given to that goddess, and to Vishnu, Krishna, and Rama, who are described and represented of "hyacinthine hue." Among these names are Syama, Shyamala, &c.

**SI**, in *Geography*, a town of China, of the third rank, in Ho-nan; 50 miles N.W. of Kouang.

**SI**, or **SIA**, a town of China, of the second rank, in Chan-fi. N. lat.  $36^{\circ} 40'$  E. long.  $110^{\circ} 31'$ .

**SI**, in *Music*, a name in finging, given by the French to the sharp 7th of the key of C, to preclude the embarrassment of the mutations in solmifation. (See **HEXACHORD**, and **MUTATIONS**.) A similar expedient had been often attempted by various authors; but none had been so generally adopted as this, which however was long solely confined to France; nor is it yet general all over Europe. And we think that the manner in which the French syllabize not only vocal but instrumental music, is subject to very material objections; it only provides for one key. If the new syllable *fi* had been used for the sharp 7th of every key, as well as that of *ut* or C natural, and *la* for every key-note or *tonique* in minor keys, it would have exempted the *principianti* in finging from much perplexity. There is no certain name for any note, except in the key of C, *ut, re, mi, fa, sol, la, si, ut*; and whether B is flat, natural, or sharp, it is equally denominated *fi*; as C, whether natural, flat, or sharp, is always called *ut*. When D is the key-note, it is named *re*; when it is the 3d of the key of B $\flat$ , or 4th of A, it still retains the name of *re*.

Malcolm, in the year 1721, was the first who openly censured the hexachord, which Dr. Pepusch, in 1731, defended with some warmth, by giving the best and clearest explanation of their use and importance, not only in finging but composition, in regulating the answers to fugues. Fouchs, Padre Martini, Sala, and the most respectable Italian and German theorists, still adhere to the solmifation which has produced so many great composers and fingers during the two last centuries. We have given our opinion fully on the subject in the article **SERRA**, a Roman master, who proposed a new method of naming the intervals in cultivating the voice. See **SERRA**.

The original introduction of this syllable is attributed by Mercennus and other writers to one Le Maire, a French musician, who laboured for thirty years to bring it into practice; but he was no sooner dead than all the musicians of his country made use of it. However, it has been the more general opinion, that the syllable *fi* was introduced into the scale by Ericius Puteanus of Dort, who lived about the year 1580. M. Bourdelot ascribes the introduction of this syllable into the scale to a Cordelier, about the year 1675; and he adds, on the testimony of the abbé de la Louette, that it was invented, or a second time brought into practice, by one Metru, a famous finging-master at Paris, about the year 1676; and Bonet inclines to think, that the honour of the invention might be due to the Cordelier, but that the merit of reviving it is to be ascribed to Metru. Bourdelot insinuates, that though the use of the syllable *fi* is much ap-

proved of by the French musicians, yet in Italy they disdain to make use of it, as being the invention of a Frenchman. Hawkins's Hist. of Music, vol. i. p. 435.

The French are not yet agreed to whom they are obliged for the syllable *si*; some say it was Nevers, some Le Maire, and other claimants are mentioned by Rousseau; but not being quite satisfied with its utility, we shall bestow no pains in verifying the claims of an imperfect invention.

*Si Actio*, in *Law*, the conclusion of a plea to the action, when the defendant demands judgment, if the plaintiff ought to have his action, &c.

SIABE', in *Geography*, a town of Persia, in the province of Segestan, or Seitlan.

SIABISCH, a river of Russia, which runs into the Abakan, near Bankalova, in the government of Kolyvan.

SIADY, a town of Samogitia, seated on a lake; 33 miles N. N. W. of Miedniki.

SIAGNE, a river of France, which runs into the Mediterranean, N. lat.  $43^{\circ} 31'$ . E. long.  $7^{\circ}$ .

SIAGONAGRA, a name given by some medical writers to the gout in the jaws.

SIAKA, in *Geography*, a town of Japan, in the island of Ximo; 12 miles W. of Taifero.

SIA-KOH, a mountain of Persia, in the province of Irak; 50 miles E. N. E. of Kom.

SIAL, a small island near the coast of Egypt, which forms a harbour in the Red sea. N. lat.  $24^{\circ} 30'$ . E. long.  $35^{\circ} 2'$ .

SIALACOORY, a town of Hindoostan, in Cochin; 30 miles N. E. of Cranganore.

SIALISMUS, formed from *σάλω*, *saliva*, a word used by the ancients to express a discharge of saliva, brought on by the holding hot things in the mouth; and by us for a salivation by mercury.

SIALO, in *Geography*, a town on the E. coast of the island of Sibiu. N. lat.  $9^{\circ} 53'$ . E. long.  $123^{\circ} 30'$ .

SIALOCHI, a term used by the ancients to express such persons as had a plentiful discharge of saliva, by whatever means. Hippocrates uses it for a person having a quinsy, who discharges a very large quantity of saliva. Others express by it persons, whose mouths naturally abound with a bitter saliva; and others, such persons as, from having a very large tongue, spit into people's faces while talking with them.

SIALOGOGUES, in *Medicine*, from *σάλω*, *saliva*, and *γωγω*, *I excite*, comprehend all such medicines as increase the flow of saliva.

The substances which operate upon the salivary glands, so as to excite them to pour out their fluid in increased quantities, are of two kinds; namely, those which may be called external, and which, when applied within the mouth, stimulate the excretories of saliva and mucus, opening thereby their acrid qualities; and those which are administered internally, and operate through the medium of the circulation.

It seems to be a salutary provision of nature, that when any acrid matter is applied to the sensible parts of the tongue and internal surface of the mouth, a quantity of saliva and mucus should be poured out to wash it off, or to defend those parts from its irritating effects. Whence, by the continued application of acrid substances, a considerable evacuation of the vessels of those parts is produced. By emptying the salivary glands and mucous follicles, they produce an afflux of fluids from all the neighbouring vessels to a considerable extent. Whence it will be readily understood, that these masticatories may relieve rheumatic congestions, not only in the neighbouring parts, as in the case of tooth-ache, but also

congestions or inflammatory dispositions in any part of the head, supplied by the branches of the external carotid.

Many substances are resorted to for this purpose, and chiefly the warm and acrid vegetables; indeed every substance that proves sharp and heating to the tongue, or internal surface of the mouth, will answer the end. The angelica is a mild and agreeable sialagogue; the imperatoria more acrid; and the pyrethrum more acrid still, and therefore more commonly employed. Other substances might be enumerated, but it may be enough to add, that a bit of fresh horse-radish root, held in the mouth, and chewed a little there, is as effectual as any.

The only medicine which we possess, that is capable of exciting a flow of saliva when taken internally, is mercury. In its crude and simple state of quicksilver, however, it is perfectly inert, and exerts no influence whatever upon the living body, until it is oxydated, or combined with other materials. Its operation then, as Dr. Cullen has ably demonstrated, is not, as was formerly supposed, by any chemical action on the fluids of the body, by which they are attenuated, and thus made to pass off more readily through the excretory ducts; but by a general stimulant effect upon the vascular system, and especially upon the various excretories of it. When blood is drawn from a person under the full influence of mercury, it exhibits no appearance of any diminution of consistence; but, on the contrary, it is always found in the same condition as in inflammatory diseases.

It will not be necessary to enter into detail in this place respecting the mode of administering mercury as a sialagogue, since that has already been done under the head of *LUES Venerea*, for which disease principally it is so exhibited. In this disease, indeed, as well as in diseases of the liver, in hydrocephalus, and some other maladies, it is not administered with a view to the evacuation from the salivary glands; its operation as a sialagogue is rather looked upon as the test of its full influence on the constitution, than as the means of its remedial power. See Cullen, *Materia Medica*, part ii. chap. 17.

During the prevalence of a chemical theory, to which the discovery of the importance of oxygen in the animal economy gave rise, and when it was supposed that the nitric acid had been found to be a substitute for mercury in the cure of syphilis, it was even maintained that this acid acted in a similar manner upon the salivary glands, and was, in fact, a powerful sialagogue. Farther experience, however, while it disproved the antiveneal powers of this acid, disproved also its virtues as a sialagogue, except indeed it might influence the excretory ducts of the glands externally, that is by its acrid qualities in the act of being swallowed.

SIALUSSIEB, in *Geography*, a town of the Arabian Irak, on the Euphrates; 8 miles E. of Sura.

SIAM, a country of Asia, the name of which is of uncertain origin; but probably derived from the Portuguese, in whose orthography Siam and Siaō are the same; so that Sian, or Siang, might be preferable, as Loubere has suggested, to Siam; and the Portuguese writers in Latin call the natives "Siones." The Siamese style themselves "Tai," or freemen, and their country "Meuang Tai," or the kingdom of freemen. The Portuguese might possibly derive the name Siam from intercourse with the Peguese. "Shan," however, is the oriental term. Before the recent extension and encroachments of the Birman empire, the rich and flourishing monarchy of Siam was regarded as the chief state of exterior India; but some of its limits are not now easily ascertained. On the west of the Malayan peninsula some possessions may remain to the south of Tanaferim; and on the eastern side of that Chersonese, Ligor may

may mark the boundary. On the west, a chain of mountains divides Siam, as formerly, from Pegu; but the northern province of Yunshan seems to belong to the Birmans; who extended their territory, in this part, to the river Maykang; and the limits may perhaps (says Pinkerton) be a small ridge running E. and W. above the river Anan. To the S. and E. the ancient boundaries are fixed; the ocean, and a chain of mountains, dividing Siam from Laos and Cambodia: so that, according to the ancient description of this kingdom, it may be considered as a large vale between two ridges of mountains. The northern boundaries, as defined by Loubere, evince that Siam has lost little in that quarter. His city Chiamai is probably Zamec, fifteen days' journey beyond the Siamese frontier. The northern limit is therefore at  $19^{\circ}$ , and not at  $22^{\circ}$ , as he erroneously states its latitude; and therefore the length of the kingdom may be about  $10^{\circ}$ , or near 700 British miles, and about one-half of this not above 70 miles in medial breadth. Or its admeasurement may be more accurately stated from about  $11^{\circ}$  of N. lat. to  $19^{\circ}$ ; being in length of about 550 British miles, by a breadth of 240.

This kingdom is divided into ten provinces, *viz.* Supthia, Bancok, Porcelon, Pipli, Camphine, Rappri, Tanaferim, Ligor, Cambouri, and Concacema, each of which has its governor respectively. Of these provinces we have the following short notices. Bancok is situated above seven leagues from the sea, and in the Siamese language is called Fou. Its environs are embellished with delicious gardens that furnish the natives with fruit, which is their chief nourishment. See BANCOK.

Tanaferim is a province abounding in rice and fruit-trees; it has a safe and commodious harbour, admitting vessels of all nations; and in this province the people find more ample resources of subsistence than in the other parts of the monarchy. (See TANAFERIM.) Cambouri, on the frontiers of Pegu, carries on a considerable trade in the commodity called by the French eagle-wood, elephants'-teeth, and horns of the rhinoceros. The finest varnish is also procured from this province. Ligor affords a kind of tin, called by the French calain, the calin of the Portuguese. (See LIGOR.) Porcelon was formerly a distinct sovereignty, and produces dyeing woods and precious gums.

The capital city of the kingdom has been called Siam, by the ignorance of Portuguese navigators. In the native language the name approaches to the European enunciation of Yuthia, or Juthia; it is situated on an isle formed by the river Meinam or Menam. Its walls in Loubere's time were extensive; but not above a sixth part was inhabited. Its condition, since it was delivered from the Birman conquest in 1766, has not been described. The royal palace was on the north, and on the east there was a causeway, affording the only free passage by land. Distinct quarters were inhabited by the Chinese, Japanese, Cochinchinese, Portuguese, and Malays. The temples, pyramids, and royal palaces seem to have been much inferior in all respects to those of the Birmans. See JUTHIA.

The other chief towns in the Siamese dominions are Bancok, at the mouth of the Meinam, Ogmoo, and others on the eastern coast of the gulf of Siam. On the western, D'Anville marks Cham, Cini, and others as far as Ligor. Along the banks of the great river are Louvo and Porcelou, with others of inferior note. Louvo was a royal residence for a considerable part of the year. In general, these towns were only collections of hovels, sometimes surrounded with a wooden stockade, and rarely with a brick wall. In the south-west, Tanaferim and Merghli may be regarded as possessions belonging to the Birman empire, and the remain-

ing fragment of the Siamese territory in that quarter presents no considerable town; though villages appear in Junkfeylon and some of the other isles. Kämpfer, in an account of his voyage to Japan in 1690, describes two remarkable edifices near the capital: the first is a famous pyramid, and called Puka Thon, erected for the commemoration of a victory obtained, on the spot where it stands to the N.W., over the king of Pegu. This magnificent structure is enclosed by a wall, and is 120 feet high, varying in form at its different stages, and terminating in a slender spire; the second edifice consists of two squares to the east of the city, surrounded by a wall, and separated by a channel of the river. These squares contain many temples, convents, chapels, and columns, particularly the temple of Berklam, with a grand gate ornamented with statues and various carvings; the other decorations appear by Kämpfer's account to have been exquisite.

Our principal sources of information with regard to Siam are the publications of La Loubere, who went as ambassador from Louis XIV. to the king of Siam, and those of the French missionaries, of which, that from the papers of the bishop of Tabraca by Turpin, in 1771, is the most important. According to the account of the latter writer, the people of Laos and Pegu have established a considerable colony in Siam, since their countries were ravaged by the Birmans. Here are also many Malays, and the ancient kings had a guard of Japanese, which exhibits, in a striking point of view, the intercourse that subsisted among oriental nations.

With regard to the history of Siam, we shall content ourselves with observing, that previously to the Portuguese discoveries, this country was unknown to Europeans. According to Loubere's account, the first king of the Siamese commenced his reign in the year 1300 of their epoch, or about 756 years after the Christian era. Since the Portuguese discovery, their wars with Pegu, and occasional usurpations of the throne, constitute the principal topics of their history. In 1568 the Peguese king declared war on account of two white elephants, which the Siamese refused to surrender; and after prodigious slaughter on both sides, Siam became tributary to Pegu; but about the year 1620, raja Hapi delivered his crown from this servitude. In 1680, Phalcon, a Greek adventurer, being highly favoured by the king of Siam, opened an intercourse with France, for the purpose of supporting his ambitious designs; but they were punished by his decapitation in 1689, and the French connection was thus terminated. From Turpin, who has extended the history of Siam to the year 1770, we learn, that the first king began to reign about 1444 years before Christ, and that he had forty successors before the epoch of the Portuguese discovery, or the year 1546, many of whom were precipitated from the throne on account of their despotism. Nevertheless, as these forty kings cannot be supposed to have reigned more than ten years each, at a mean computation, the first historical date cannot ascend beyond the year 1100 after Christ, instead of 1444 years B.C. One of the most remarkable events, after the French had evacuated Siam, is the war against the kingdom of Cambodia, which was reduced to the necessity of seeking the protection of Cochinchina. The Siamese army, having advanced too far into the country, was destroyed by famine; and their fleet, though it destroyed the town of Ponteamas, with 200 tons of elephants' teeth, had little success. In 1760 a signal revolution happened in Siam, preceded by violent civil wars between two rival princes. According to Turpin's statement, the Birmans, a people of the kingdom of Ava, had, in 1754, languished five years under the Peguese domination. Having lost by death  
their

their king, queen, and most of their princes, they lamented their humiliation and servitude, and anxiously sought for a deliverer. With this view they selected one of their companions, named Manlong, a gardener, who, singularly qualified for the office they devolved upon him, by corporeal and mental endowments, undertook to rescue them from the yoke of tyrants, on condition of their cutting off the heads of all the little subaltern tyrants whom the Peguese had sent to oppress them. They readily submitted to his terms; and after the massacre, Manlong was proclaimed king. Having prepared a force, and established a discipline which rendered the Birmans almost invincible, he began by the capture and complete ruin of the city and port of Siriam, which took place about the year 1759; and advancing to Martavan and Tavail, the new monarch received information of the riches of Siam, and formed the design of its conquest. He began by sending 30 ships to pillage the cities of Mergli and Tanaferim, and this success led him to flatter himself that he should be able, with great ease, to subdue the whole kingdom of Siam. The court of Siam, hearing of this irruption, sent to the bishop of Tabraca, to request that he would arm the Christians, who amounted only to the number of 100, and yet acquitted themselves with greater honour than the pusillanimous multitude. The Birman sovereign, being at the distance of three days' march from Yuthia, the capital, died in consequence of an abscess. The suburbs, however, on the Dutch quarter were ravaged and burnt; and the surrounding country was exposed to a thousand cruelties. The death of Manlong delivered the Siamese capital; the youngest of his sons having assumed the sceptre, found himself under the necessity of regaining his own kingdom, in order to stifle any revolt. The Siamese sovereign, however, having rashly pronounced a sentence of death against the favourite of his brother, was forced to abdicate the throne; and in consequence of this event he became a Talapoin, or monk, in May 1762, and many of his nobles followed his example. Siam remained in a state of security, upon the report that the new prince of the Birmans had been dethroned upon his return to Ava; and that his elder brother, who had succeeded, had no wish to make conquests. This pacific monarch dying suddenly, a pretence of war was afforded by the assistance which the Siamese had given to a rebel Birman governor. In January 1765, the Birmans attacked Mergli and took it; and then proceeded to Tanaferim, which they reduced to ashes. Flushed with success, the general of the Birmans marched against Yuthia, not doubting that the conquest of the capital would induce other cities to submit. The provinces on the north-west of the royal city were ravaged; and the inhabitants saved themselves from death or slavery by dispersion into forests, where they participated the food of wild beasts. The Siamese, threatened with speedy and total destruction, reunited their forces; but though they fought with ardour, their sanguinary defeat subjected their country to the power of their conqueror. The fields, ravaged by the consuming flames, presented nothing to them but ashes, and famine became more terrible than war. The victorious Birmans built, at the confluence of two rivers, a town, or rather a fortified station, which they called Michoug. The Siamese, on their part, attempted to fortify the capital, and earnestly solicited the assistance of two English vessels which happened to arrive. The captain of one of them consented to defend the capital, on condition of being supplied with cannon and ammunition; but the jealous Siamese insisted that he should first lodge his merchandizes in the public magazine. With this condition he complied, and going on board his ship, harassed the enemy, and destroyed their forts, so that every day was

marked either by their defeat or flight. But demanding more ammunition, the dastardly court became afraid, that the English captain, with his single ship, would conquer this ancient monarchy. Its indignant captain withdrew, after seizing six Chinese vessels, whose officers received from him orders upon the king of Siam to the amount of the merchandizes which had been lodged in the public treasury. Upon his retreat, the Birmans, finding no opposition, spread universal desolation, and consigned even their temples to the flames. Instead of recurring to arms, the superstitious monarch and his ministers reposed their whole confidence in their magicians. A Siamese prince, indeed, who had been banished to Ceylon, raised a little army, and returned to the assistance of his country; but the distracted court of Siam sent forces to oppose their deliverer. Many of the Siamese, justly provoked by this conduct, joined the Birmans, who in March 1766 again advanced, after having been repulsed by the English captain, to within two leagues of the capital. In September 1766, the Birmans seized a high tower, at the distance of about a quarter of a mile from the city, and raised a battery of cannon, which gave them an absolute command of the river. In this state of urgent danger, 6000 Chinese were charged with the defence of the Dutch factory, and of a large adjacent temple. The Birmans, in consequence of previous skirmishes and a subsequent assault, seized on five considerable temples, which they converted into fortresses; but in another assault they were compelled to retire. The Siamese officers, eager to secure the magazines of grain, as a future resource, produced an immediate famine; which, followed by a contagious disorder or pestilence, occasioned the most dreadful devastation. The Dutch factory was in vain defended by the Portuguese and Chinese; and after a siege of eight days, it was taken and reduced to ashes. The whole Christian quarter of the city shared the same fate; and the virgins were obliged to marry the first young men that presented themselves, in order to be protected by the matrimonial tie, which the Birmans reverence. The Birmans, demanding an unconditional surrender, assaulted the city, and captured it on the 28th of April 1767. The wealth of the palaces and temples was consumed by the flames, or abandoned to the soldiery. The golden idols were melted; and the victors, finding that their avarice had been sacrificed to their fury, recurred to acts of violation and cruelty. The great officers of the kingdom were laden with irons, and condemned to the galleys. The king, attempting to escape, was massacred at the gate of his palace. When nothing remained for these conquerors to destroy, they resumed their march to Pegu, accompanied, among other captives, with the remaining princes and princesses of the royal blood of Siam. In June the Birmans quitted Siam, after having burnt the town of Michoug, soon after its construction.

When the Birmans evacuated their conquest, the Siamese issued from their forests, and superstitiously directed their first rage against their gods, for having abandoned them to a destructive enemy. Availing themselves of the wealth which accrued from the statues, filled by superstitious persons with gold and silver, who expected to find them when they revisited this world, they proceeded to elect a leader; and Phai-Thaë, an officer of acknowledged ability, was the object of their choice. This new prince displayed considerable bravery and talents; and in the year 1768 suppressed a rebellion that was instigated against him. The Birmans in vain attempted to renew their incursions into the Siamese territory: they were repulsed, and afterwards obliged to turn their arms against the Chinese, who were defeated in their turn. For further particulars with regard to the history of Siam, see *BIRMAN Empire*. Indeed, if the Birman empire maintains

maintains its present extent, Siam, we can have little doubt, will ere long be deprived of its independence. But it is an event not, perhaps, less probable, that the Birman empire itself will fall into confusion, and be dismembered.

Every thing we are told respecting the government, the laws, the literature, the arts, and personal qualities of the Siamese, indicates a corresponding state of advancement with that of the Birmans. That the religion of the Siamese is the same with that of the Birmans, and derived from the same origin as that of the Hindoos, there seems to be sufficient evidence. Sommona-Codam, mentioned by Loubere as the chief idol of Siam, is interpreted by competent judges to be the same with the Boodh of Hindoostan. The sacred language called Bali is of the same origin: the most esteemed book seems to be the Vinac, and the precepts of morality are chiefly five; *viz.* not to kill, not to steal, not to commit uncleanness, not to lie, and not to drink any intoxicating liquor. Loubere has given a translation of a more minute code of morals, chiefly compiled for the use of persons dedicated to religion, whom he calls Talapoins. Their laws are said to be in high reputation all over the East; and it is not certain, whether, like those of the Birmans, they are of Hindoo, or of indigenous birth. Their system of legislation is represented by all writers on this country, as extremely severe in its functions; death or mutilation being punishments of unimportant offences. The Siamese imitate the Chinese in their festival of the dead; and in some other of their rites. The government of Siam is despotic, and the sovereign, as among the Birmans, is revered with honours almost divine. The succession to the crown is hereditary in the male line. The population has not been accurately ascertained, nor have we any documents for this purpose. Allowing to the Birman empire more than fourteen millions, as some have stated, the Siamese dominions may probably be peopled by about eight millions. However, Loubere assures us in his time, that from actual enumeration, there were only found, of men, women, and children, 1,900,000. Loubere says that the Siamese had no army, except a few royal guards; but Mandelso estimated the army, which may be occasionally raised, at 60,000, with no less than 3000 or 4000 elephants. The navy is composed of a number of vessels of various sizes, which display a singular fantastic elegance, like those of the Birmans; and naval engagements frequently occur. The revenues of this sovereignty are of uncertain computation. Mandelso describes them as arising from the third of all inheritances, from trade, conducted by royal agents, annual presents from the governors of provinces, duties imposed on commerce, and the discovery of gold, which seems to be a royal claim. Tin is also a royal metal, except that found in Junkfeylon, which is abandoned to the adventurers. Loubere adds a kind of land-tax, and other particulars, among which is the royal domain.

Siam appeared to the French, in the reign of Louis XIV. to be of considerable political importance; for this monarch was ambitious of forming permanent settlements, by rendering it a rich mart of Indian commerce. If we had any apprehension that the Birmans would become dangerous to our possessions in Bengal, our alliance with Siam might be highly serviceable. In a merely commercial point of view, as it may be difficult to preserve the friendship of both the Birmans and the Siamese, it is not easy to determine from which state superior advantages might be derived. If directed by European policy, Siam would form strict alliances with the more easterly states of exterior India, as a common defence against the growing preponderance of the Birmans.

As to the manners and customs of the Siamese, as they

have embraced a branch of Hindoo faith, they are rather Hindoostanic than Chinese; though its situation is central between the vast countries of China and Hindoostan. Loubere has given a detailed account of the Siamese manners. The females are under few restraints, and marry at an early age, and are past parturition at forty. Marriages are conducted by female mediation, and a priest or magician is usually consulted concerning the propriety of an alliance. On the third visit the parties are considered as wedded, after the exchange of a few presents, without any farther ceremony, civil or sacred. Polygamy is allowed, more from ostentation than any other motive; and one wife is always acknowledged as supreme. Royal marriages, from considerations of pride, are sometimes incestuous; nor does a king hesitate to espouse his own sister. Divorce is seldom practised; but the rich may chuse a more compliant wife without dismissing the former. Few women become nuns, till they are advanced in years. The Siamese funerals resemble those of the Chinese. On this occasion, the Talapoins sing hymns in the Bali tongue. After a solemn procession the body is burnt on a funeral pile of precious woods, erected near some temple; and the magnificence of the spectacle is enhanced by theatrical exhibitions, in which the Siamese are said to excel. The tombs are pyramidal, and those of the kings are large and lofty. The common food of the Siamese consists of rice and fish; they also eat lizards, rats, and several kinds of insects. The buffaloes yield rich milk; but butter would melt and become rancid; and cheese is unknown.

In Siam little animal food is used; the mutton and beef being very bad. The doctrine of Boodh inspires the Siamese with horror at the effusion of blood. The houses are small, and constructed of bamboos, upon pillars, in order to guard against inundations, which are common. The palaces only exceed common habitations by occupying a wider space, and being constructed of timber, with a few ornaments. They are also more elevated, but have never more than one floor. With regard to their persons, the Siamese are rather small, but well made. The figure of the countenance, says Kämpfer, both of men and women, has less of the oval than of the lozenge form, being broad, and raised at the top of the cheeks; and the forehead suddenly contracts, and is almost as pointed as the chin. Their eyes, rising towards the temples, are small and dull; and the *white* is commonly completely yellow. Their cheeks are hollow; mouth very large, with thick pale lips, and teeth blackened by art; the complexion coarse, brown mixed with red, to which the climate greatly contributes. From this description the Siamese appear to be much inferior in personal appearance to the Birmans; and to approach rather to the Tartaric or Chinese features.

The dress of the Siamese is slight, clothes being rendered almost unnecessary by the warmth of the climate. A muslin shirt, with wide sleeves, and a kind of loose drawers, are almost the only garments of the rich, a mantle being added in winter, and a high conic cap upon the head. The women use a scarf instead of the shirt, and the petticoat is of painted calico; but with this slight dress they are extremely modest.

The Siamese are said to excel in theatrical amusements; the subjects being taken from their mythology, and from traditions concerning their ancient heroes. Their ordinary amusements consist of races of oxen, and those of boats, the combats of elephants, cock-fighting, tumbling, wrestling, and rope-dancing, religious processions, illuminations, and beautiful exhibitions of fire-works. The men are generally very indolent, and fond of games of chance; while  
the

the women are employed in works of industry. Although the Siamese are indolent, they are ingenious, and some of their manufactures deserve praise; nevertheless, the ruinous and despotic avarice of the government crushes industry by the uncertainty of property. They are little skilled in the fabrication of iron or steel, but excel in that of gold, and sometimes in miniature painting. The common people are mostly occupied in procuring fish for their daily food, while the superior classes are engaged in a trifling traffic.

The language of the Siamese, called "T'hay," according to Dr. Leyden's account of it (*Asiatic Researches*, vol. x. p. 244.), appears to be in a great measure original; but there is reason to conjecture, that it is not different from that of the Birmans. To this purpose it is alleged, that Siamese dramatists used to perform in the Birman dominions, which is not probable, unless the language were common. Dr. Leyden says, that it is more purely monosyllabic, and more powerfully accented, than any of the Indo-Chinese languages. It certainly is connected, in some degree, with some of the Chinese dialects; especially the Mandarin or Court language, with which its numerals, as well as some other terms, coincide, but these are not very numerous. It borrows words freely from the Bali, but contracts and disguises more the terms which it adopts, than either the Ruk'heng or the Barma. In its finely modulated intonations of sound, in its expression of the rank of the speaker, by the simple pronouns which he uses, in the copiousness of the language of civility, and the mode of expressing esteem and adulation, this language resembles the Chinese dialects, with which also it coincides more nearly in construction than either Barma or Ruk'heng. Its construction is simple and inartificial, depending almost solely on the principle of juxtaposition. Relative pronouns are not in the language; the nominative regularly precedes the verb, and the verb precedes the case which it governs. When two substantives come together, the last of them is for the most part supposed to be in the genitive. This idiom is consonant to the Malayu, though not to the Barma or Ruk'heng, in which, as in English, the first substantive has a possessive signification. Thus, the phrase, *a man's head*, is expressed in Barma and Ruk'heng, by *lu-k'haung*, which is literally *man-head*; but, in Siamese, it is *kua-khon*, and in Malayu, *kepala orang*, both of which are literally *head-man*. A similar difference occurs in the position of the accusative with an active verb, which case in Barma and Malayu generally precedes the verb, as *tummaing cha*, literally *rice eat*; but in Siamese follows it, as *ken kaeo*, literally *eat rice*, which corresponds to the Malayu, *makan nasi*. The adjective generally follows the substantive, and the adverb the word which it modifies, whether adjective or verb. Whenever the name of an animal, and, in general, when that of a species or class, is mentioned, the generic, or more general name of the genus to which it belongs, is repeated with it, as often happens in the other monosyllabic languages, as well as in the Malayu. In the position of the adverbial particle, the Malayu often differs from the Siamese; as *Mana pargi*, literally *where go*, but in Siamese, *pa'i hnei*, *go where*. The Siamese composition is also, like that of the Barma, a species of measured prose, regulated solely by the accent and the parallelism of the members of the sentence; but in the recitative the Siamese approaches more nearly to the Chinese mode of recitation, and becomes a kind of chaunt, which different Brahmins assured Dr. Leyden is very similar to the mode of chaunting the Samaveda.

The T'hay coincides occasionally, even in simple terms, both with the Barma and Malayu; but these terms bear fo

small a proportion to the mass of the language, that they seem rather the effect of accident or mixture, than of original connection.

The T'hay or Siamese alphabet differs considerably in the power of its characters from the Bali; though it not only has a general resemblance to it in point of form, but also in the arrangement of the character. The vowels, which are twenty in number, are not represented by separate characters, but by the character corresponding to the short *akar*, variously accented; excepting the vocalic *ru* and *lu*, which are only variations of the *r* and *l* consonants. The consonants are thirty-seven in number, and are not arranged by the series of five, like the Deva-nagari and Bali, but the first series, *ka*, consists of seven letters; the second series, *cha*, of six; the third series, *ta* or *da*, of six; the fourth series, *ba* or *pa*, of eight; the fifth series, *ja*, of four; and the last series, *sa*, of six, including the vocalic *akar*, though two of them are not in common use. Each of these letters is varied by sixteen simple accentuations, and by thirty-six complex ones. The letters *ka*, *nga*, *ta*, or *da*, *na*, *ma*, *ba* or *pa*, are also final consonants. Hence it is easy to perceive the near approximation of the Siamese to the delicacy of the Chinese accentuation; while in other respects, the alphabet is considerably more perfect, than in the Mandarin or Court language of the Chinese, which has neither the same variety of consonants, nor admits so many, in the close of a syllable. The Siamese pronunciation, even of consonants, corresponds very imperfectly to the European mode: *r* and *l* are generally pronounced *n* in the close of a syllable; *h* is often prefixed to a consonant; but from the total suspension of the voice in pronouncing syllables which terminate in a consonant, no aspiration can be pronounced after them; *ma* and *ba*, *tya* and *chya*, are often difficult to be distinguished in pronunciation, as are *ya* and *ja*, *kyé* and *chyé*, with other combinations. From this circumstance, many combinations of letters are pronounced in a manner somewhat different from that in which they are written.

The first European who attempted the study of Siamese literature, was the learned Gervaise, but his lucubrations have never been published. The learned and indefatigable Hyde procured from the Siamese ambassador at London, an imperfect copy of the Siamese alphabet, which has been published by Greg. Sharpe, in the "*Syntagma Dissertationum*," 1767. It is inferior to La Loubere's alphabet in accuracy, though it contains a greater number of compound characters. La Loubere's alphabet contains three forms of the *sa*, corresponding to the Nagari; but the *sha* and *sh'ba*, being disused in common pronunciation, are commonly omitted both in the alphabet and in modern MSS.

The Siamese or T'hay language contains a great variety of compositions of every species. Their poems and songs are very numerous, as are their Cheritras, or historical and mythological fables. Many of the Siamese princes have been celebrated for their poetical powers, and several of their historical and moral compositions are still preserved. In all their compositions, they either affect a plain simple narrative, or an unconnected and abrupt style of short, pithy sentences, of much meaning. The books of medicine are reckoned of considerable antiquity. Both in science and poetry, those who affect learning and elegance of composition, sprinkle their style copiously with Bali. The laws of Siam are celebrated all over the East, and La Loubere has mentioned three works of superior reputation, the *Pra-Tam-non*, the *Pra-Tam-Ra*, and the *Pra-Raja-Kam-manot*. Of these, the first is a collection of the institutions of the ancient kings of Siam; the second is the constitutional code

of the kingdom, and contains the names, functions, and prerogatives of all the officers; the third, which is about 150 years old, contains additional regulations. Of these, the first is the most celebrated and the most deserving the attention of Europeans.

The T'hay exhibits considerable variety of measures in composition, and frequently introduces several of them in the same manner as is frequently done in Brij'h, Punjabi, and Sik'h compositions. The most frequent measure, however, among the T'hay, as among the Ruk'hong and Barma, seems to be that denominated *râp*, which consists of four long syllables, but admits occasionally of one or more intercalary short ones: the Jâ-ni, which consists of five syllables, the Chô-bang of six, the Pat'namang of seven, the Jesunta of eight, are also frequently employed. The Siamese are not deficient in literature, and their modes of education are well explained by Loubere.

From Mandello we learn, that the commerce of the capital of Siam consisted in cloths imported from Hindoostan, and various articles from China; in exports of jewels, gold, benjoin, lacca, wax, tin, lead, &c. and particularly deer-skins, of which more than 150,000 were sold annually to the Japanese. Rice was also exported in great quantities to the Asiatic isles. The king was, by a ruinous policy, the chief merchant, and had factors in most of the neighbouring countries. The royal trade consisted in cotton cloths, tin, ivory, saltpetre, rack, and skins sold to the Dutch. A late writer informs us, that the productions of this country are prodigious quantities of grain, cotton, benjamin; sandal, aguello, and Japan woods; antimony, tin, lead, iron, load-stones, gold, and silver; sapphires, emeralds, agates, crystal; marble, and tambac. Siam, in respect of fertility, loco-position, and productive labour, possesses commercial advantages of the same nature with those of the Birman empire; but on the coast at least, the climate is far from being healthy.

The two first months of the Siamese year, corresponding with our December and January, form their whole winter; the third, fourth, and fifth, belong to that portion which is called their little summer; and the seven others to their great summer. As they lie north of the line, their winter corresponds with our's, but it is almost as warm as a French summer. The little summer is their spring; autumn is unknown in their calendar; the winter is dry, and is distinguished by the course of the wind, which almost constantly blows from the north, and is refreshed with cold from the snowy mountains of Thibet, and the bleak wastes of Mongolia.

We have already described this country as a wide vale between two high ridges of mountains; but compared with the Birman empire, the cultivated land is not above half the extent either in breadth or length. Less industrious than the Birman, the agriculture of the Siamese does not extend far from the banks of the river, or its branches; so that towards the mountains there are vast aboriginal forests filled with wild animals, whence they obtain the skins which are exported. The rocky and variegated shores of the noble gulf of Siam, and the size and inundations of the Meinam, conspire with the rich and picturesque vegetation of the forests, illumined at night with crowds of brilliant fireflies, to impress strangers with admiration and delight.

The soil towards the mountains is parched and infertile; but on the shores of the river consists, like that of Egypt, of a very rich and pure mould, in which a pebble can scarcely be found; and the country would be a terrestrial paradise, if its government were not so despotic as to be justly reckoned far inferior to that of their neighbours the

Birman. Rice of excellent quality is the chief product of their agriculture; wheat is not unknown; pease and other vegetables abound; and maize is confined to their gardens. The fertility of Siam depends in a great degree, like that of Egypt on the Nile, on their grand river Meinam, and its contributory streams; for an account of which, see MEINAM.

Of the lakes of this country little is known: a small one, however, lies in the east of the kingdom, which is the source of a river that flows into that of Cambodia. To its extensive ranges of mountains, including the kingdom on the east and west, we have already referred. A small ridge also passes from east to west, not far north of Yuthia, called by Loubere Taramamon. The forests of the country are large and numerous, and produce many valuable woods. Its chief animals are elephants, buffaloes, and deer. The elephants in particular are distinguished for their sagacity and beauty; and those of a white colour are treated by the Siamese with a kind of adoration, as they believe the soul of such is royal. Wild boars, tigers, and monkeys, are numerous. The reports of the mineralogy of Siam are various. Mandello, or rather his translator Wicquefort, who added, about the year 1670, the accounts of Pegu, Siam, Japan, &c. informs us, that Siam contains mines of gold, silver, tin, and copper; and Loubere suggests, that they were anciently more diligently wrought, as the ancient pits indicate; not to mention the great quantity of gold, which must have been employed in richly gilding the idols, pillars, ceilings, and even roofs of their temples. In his time no mine of gold or silver, worth the labour of being wrought, could be found. The mines chiefly wrought by the Siamese were those of tin and lead. The tin, called "calin" by the Portuguese, was sold throughout the Indies; but it was soft and ill refined. Near Louvo was a mountain of load-stone, and another of inferior quality in *Junkfeilon*; which see. Pinkerton's *Geog.* vol. ii.

The Siamese, though of a melancholy turn, have no objection to lively music. They have often parties on the water, which they render very pleasant by a number of voices, and the clapping of hands, with which they beat time.

The instrument in the highest favour with them produces a sound similar to two violins perfectly in tune, played at the same time. But there is nothing more disagreeable than its diminutive, the kit of this instrument, which is a kind of rebeck, or violin with three brass strings.

Their copper trumpets very much resemble, in tone, the cornets with which the peasants of France call their cows. Their flutes are not much sweeter. They make likewise a kind of carillon with small bells, which are lively, and not disagreeable, when not accompanied by their iron drum, which stuns every one that is not accustomed to its noisy harshness. They have drums made of *terra cotta*, a baked clay, with a long and very narrow neck, but open at the bottom: they cover the drum with a buffalo's hide, and beat it with the hand in such a manner, that it serves for a bass in their concerts. Their voices are not disagreeable, and if we were to hear them sing some of their airs, we should not be displeas'd. Laborde.

SIAM, a name sometimes given to the country above described. See *ATUNTA*, and the preceding article.

SIAM, *Gulf of*, a large bay of the East Indian sea, between Cambodia and the peninsula of Malacca, having to the north Siam.

SIAMODEL, a town of Hindoostan, in the Carnatic; 13 miles N. of Nellore.

SIAMPA. See *CHIAMPA*.

SIAN, Scio, or *Cio*, a town of Africa, in Melinda.

SIANCAS, a town of South America, in the province of Tucuman; 30 miles E.S.E. of St. Salvador de Jugui.

SIANDUPADA, a town of Hindoostan, in Myfore; 13 miles S.W. of Bangalore.

SIANELLY, a town of Hindoostan, in Myfore; 13 miles S.W. of Bangalore.

SIANG, a city of China, of the second rank, in Quang-li. N. lat.  $23^{\circ} 58'$ . E. long.  $109^{\circ} 0'$ .

SIANG-CHAN, a town of China, of the third rank, in Tche-kiang; 25 miles S.E. of Ning-po.

SIANG-HIAN, a town of China, of the third rank, in Hou-quang; 40 miles S.W. of Tchang-tcha.

SIANG-TAN, a town of China, of the third rank, in Chan-fi; 20 miles S.E. of T'ing.

SIANG-YANG, a town of Corea; 28 miles N.N.W. of San-pou.

SIANG-YANG, a city of China, of the first rank, in Hou-quang, on the river Han. N. lat.  $32^{\circ} 5'$ . E. long.  $111^{\circ} 30'$ .

SIANG-YN, a town of China, of the third rank, in Hou-quang, on the Heng river; 27 miles N.N.W. of Tcheng-tcha.

SIANKE, or SYNKE, in *Natural History*, a name given by the people of some parts of the East Indies to the caryophyllus, or clove-spice. The people of the Moluccas, according to Garcias, call it *chanque*, which is only a small difference of pronunciation. The Turks and Persians call the same spice *calafiu*.

SIAO, in *Geography*, a town of China, of the third rank, in Kiang-nan; 22 miles W. of Pefu.

SIAO, an island in the East Indian sea, about 30 miles in circuit, which belongs to the sultan of Ternate. The Dutch maintain in this island a corporal, a few soldiers, and a school-master for the instruction of the children of the natives. It abounds with provisions. N. lat.  $2^{\circ} 44'$ . E. long.  $125^{\circ} 5'$ .

SIAO-CHAN, a town of China, of the third rank, in Tche-kiang; 17 miles N.W. of Chao-king.

SIAO-HE-CHAN, a small island near the coast of China. N. lat.  $37^{\circ} 54'$ . E. long.  $120^{\circ} 34'$ .

SIAO-HO-TCHAN, a town of Chinese Tartary. N. lat.  $41^{\circ} 43'$ . E. long.  $121^{\circ} 42'$ .

SIAO-NON-HOTUN, a town of Chinese Tartary. N. lat.  $41^{\circ} 24'$ . E. long.  $126^{\circ} 50'$ .

SIAO-PI-HOTUN, a town of Corea. N. lat.  $40^{\circ} 24'$ . E. long.  $125^{\circ} 26'$ .

SIAO-TEIN, a river of China, which runs into the Eastern sea, N. lat.  $37^{\circ} 21'$ . E. long.  $118^{\circ} 44'$ .

SIARA, a small town of Brasil, and capital of a district or captaincy of the same name, so called from a river which rises in the mountains, and discharges itself into the ocean in S. lat.  $5^{\circ} 30'$ . The captaincy is small, not being above 54 miles in compass. It has two fortresses, one on the north, joining to the town of Siara, and situated on a small hill on the right side of the haven, which is so shallow as to admit only small vessels; and the other, called Fort St. Luke, situated on the coast, at the mouth of a small river, navigable only by barks. This district abounds in cotton, sugar, tobacco, and Brasil wood, the usual staples of the country. The trade of the town, consisting chiefly of sugar and tobacco, is inconsiderable. S. lat.  $3^{\circ} 15'$ . W. long.  $39^{\circ} 46'$ .

SIARDEHUI, a town of Hindoostan, in the Carnatic; 8 miles N.E. of Udegherry.

SIARMAN, a town of Persia, in the province of Ma-

zanderan, on the Caspian sea; 12 miles E.S.E. of Ferrabad, or *Farabat*; which see.

SIAS, a river of Russia, which runs into lake Ladoga, near Siakoi.

SIASKOI, a town of Russia, in the government of Petersburg, near lake Ladoga; 24 miles N.E. of Nova Ladoga.

SIATGONG, a town of Hindoostan, in Bahar; 20 miles S. of Bahar.

SIATON, a town on the fourth coast of the island of Negroes. N. lat.  $9^{\circ} 21'$ . E. long.  $123^{\circ} 3'$ .

SIB, a town of Arabia, in the province of Mascat; 30 miles W.N.W. of Mascat.

SIBABA, a small island in the East Indian sea, near the fourth coast of Mindanao. N. lat.  $6^{\circ} 36'$ . E. long.  $122^{\circ} 25'$ .

SIBÆ, or SOBII, called also *Ibo* or *Saba*, in *Ancient Geography*, a people of India, on this side of the Ganges, and one of the first nations that encountered Alexander on the banks of the Acesines.

SIBALD *de Wert*, in *Geography*. See FALKLAND *Islands*.

SIBALDES, a cluster of islands near the coast of Patagonia. S. lat.  $50^{\circ} 53'$ . W. long.  $59^{\circ} 35'$ .

SIBATTA, a town of Japan, in the island of Nippon; 15 miles S.E. of Nambu.

SIBAU. See SEBOU.

SIBB, a district of the Persian empire, in the province of Mekran, governed by a chief, who resides in a small town of the same name. It consists of a very extensive plain, through the centre of which flows a river, nearly dry, in the bed of which are several groves of date-trees; but the country, generally speaking, is quite barren.

SIBBA. See SEBBA.

SIBBALDIA, in *Botany*, so named by Linnæus, in memory of sir Robert Sibbald, knt., M.D., author of *Scotia Illustrata*, a folio volume, published at Edinburgh in 1684, a considerable part of which is dedicated to plants, and in which the first species of the present genus is, for the first time, delineated.—Linn. Gen. 155. Schreb. 208. Willd. Sp. Pl. v. 1. 1567. Mart. Mill. Dict. v. 4. Sin. Fl. Brit. 345. Ait. Hort. Kew. v. 2. 199. Pursh v. 1. 211. Jussl. 337. Lamarek Illustr. t. 221. Gærtner. t. 73. —Class and order, *Pentandria Pentagynia*. Nat. Ord. *Seneciaceæ*, Linn. *Rosaceæ*, Jussl.

Gen. Ch. Cal. Perianth inferior, of one leaf, cut half way down into ten segments; its base erect; segments spreading, half-lanceolate, equal in length, permanent, the intermediate ones narrowest. Cor. Petals five, ovate, inserted into the calyx. Stam. Filaments five, capillary, shorter than the corolla, inserted into the calyx; anthers small, obtuse. Pist. Germens five, ovate, very short, in the bottom of the calyx; styles from the middle of one side of each germen, the length of the stamens; stigmas capitate. Peric. none, the closed calyx sheltering the Seeds, which are five, somewhat oblong.

Obs. The piths were found by Linnæus to be sometimes, though very rarely, doubled in number, on the same plant with other flowers that had only five. They appear to vary from five to ten.

Eil. Ch. Calyx in ten segments. Petals five, standing on the calyx. Styles from the side of each germen. Seeds five, in the bottom of the calyx.

1. *S. procumbens*. Procumbent Sibbaldia. Linn. Sp. Pl. 406. Fl. Lapp. ed. 2. 82. Fl. Brit. n. 1. Engl. Bot. t. 897. Lightf. Scot. 175. Fl. Dan. t. 32. (*Fragaria fylveitri affinis* planta, flore luteo; Sibb. Scot. p. 2.

25. t. 6. f. 1. Scotch Cinquefoil; Petiv. Herb. Brit. t. 41. f. 7.)—Leaflets wedge-shaped, three-toothed.—Native of the summits of the highest mountains of Lapland, Scotland, Switzerland, Siberia, and North America. Tournefort gathered it also in Cappadocia. The plant thrives best in a mouldering micaceous soil, flowering in June and July. The *root* is perennial and woody, throwing out many short, spreading, leafy, herbaceous, round, downy *stems*, which are slightly branched, and procumbent, except sometimes at their flowering extremities. *Leaves* on long stalks, whose base bears a pair of oblong, acute *stipulas*, like those of a rose; their *leaflets* three, on short partial stalks, wedge-shaped, inclining to ovate, green, hairy, entire, except their three large terminal teeth. *Flowers* in small terminal leafy corymbs, inconspicuous, with minute yellow *petals* and *stamens*, inserted into the thickened rim of the green leafy *calyx*. *Seeds* dry, hairy. We have noticed in *Fl. Lapp.* that Plukenet's t. 212. f. 3, cited by Linnæus, and recently copied by Pursh, belongs rather to the *Potentilla subacaulis*; nor does this figure, in essential points, resemble our *Sibbaldia*.

2. *S. erecta*. Tall Sibbaldia. Linn. Sp. Pl. 407. Willd. n. 2. Pursh n. 1. (S. n. 42; Gmel. Sib. v. 3. 186. Pentaphylloides foliis tenuissimè laciniatis, flosculis carnis; Amman. Ruth. 85. t. 15.)—Leaves in numerous linear segments. Stem erect, much branched, leafy. Petals obovate.—Native of stony ground in Siberia, flowering in August. Mr. Nuttall is recorded by Pursh, as having gathered this plant on the banks of the Missouri, in North America. The *root* is tapering, brown, probably perennial. *Stem* erect, a span high, round, downy, much branched in a corymbose manner, leafy from top to bottom, many-flowered. *Leaves* crowded, stalked, hairy, repeatedly three-cleft, with linear, obtuse, revolute, entire segments, like those of an *Artemisia*. *Flowers* somewhat racemose, small, flesh-coloured.

3. *S. altaica*. Large-flowered Sibbaldia. Linn. Suppl. 191. Willd. n. 3. "Pall. Act. Petrop. for 1773, 526. t. 18. f. 2." (S. n. 42, var. j; Gmel. Sib. v. 3. 187.)—Leaves in numerous linear segments. Stems slightly branched. Petals roundish-heart-shaped.—Found by Pallas very abundantly on the rocks of Dauria. The *stems* are but about three inches high, slender, often simple, and slightly leafy. *Flowers*, especially their *petals*, three or four times the size of the last, of which nevertheless Gmelin, and at one time Pallas himself, thought this plant a variety.

SIBBENS, or SIVVENS, in *Medicine*, an infectious disease, of a chronic nature, somewhat resembling syphilis, prevalent in the western parts of Scotland. It is said to be so denominated from the appearance of a fungous exuberance from some of the cutaneous sores, not unlike a raspberry; the word *sibben*, or *sivven*, being the Highland appellation for a wild raspberry. Whence it has also been sometimes confounded with the *yaws*, a disease of tropical climates, brought from Africa, and so denominated by the Negroes from the same fruit. See FRAMBOESIA and YAWS.

This malady is not of ancient date in Scotland. The first writer on the subject was Dr. Gilchrist, who, in the year 1765, distributed a short description of the *sibbens* among the people of Ayrshire, which was afterwards published by the Philosophical Society of Edinburgh. (See *Essays and Observations Physical and Literary*, vol. iii. art. 11.) According to tradition in the Highlands, the disease was introduced there by the soldiers of Oliver Cromwell, who laboured under the venereal disease, have garri-soned in that country. From thence it is said to have been

carried to Dumfries by a party of soldiers, who had been stationed in the north Highlands; and it is perfectly ascertained, according to Dr. Paterfon, that it was introduced into Ayrshire, about the year 1745, by people who went thither from Dumfries to buy cattle. Since that period, it has constantly prevailed in different places in that district, at different times; sometimes abating so much, both in virulence and frequency of occurrence, as to give hopes that it would entirely disappear; then breaking out again with greater violence, generally in the harvest season, and spreading over several parishes. (See Dr. Paterfon's Letter, in Beddoes's Contributions to Physical and Medical Knowledge, p. 408.) At its first appearance, it occasioned little uneasiness or apprehension to those affected with it; but it was soon discovered to be a formidable disease, resembling in character the venereal disease, and to be propagated extensively by its contagion, inasmuch that, as Dr. Gilchrist expresses it, "great are the perplexity and distress, the suspicion and terror, caused by it, wherever it comes; and hitherto nothing has been able to prevent the spreading of it." The disease differs, however, materially from *lues venerea*, though it is cured by the same remedy; the poison being introduced into the system not through the medium of the organs of generation, but commonly by the mouth and throat, in which the primary ulcerations occur.

The *sibbens* almost always begins with an inflammation of the throat, first on the *uvula* and *velum pendulum* of the palate, and afterwards on the tonsils, of a dark red colour, which is succeeded in one or two days, and sometimes so late as six or eight, by small pimples, or vesicles, which terminate in ulcers, with a white surface, and red abrupt edges. There is often also an aphthous appearance, or a series of white specks and sloughs, upon the roof of the mouth, and inside of the cheeks and lips, which commonly shews itself also at the corners of the mouth, in a small rising of the skin, of a pearl or whey-colour; upon which part also a small fungous excrecence often appears, not unlike a raspberry, which changes to a scab, and is a pretty sure sign of the disease, although there be no aphthæ or sore throat. The *uvula* is sometimes destroyed by the ulceration; and children at the breast, when thus affected in the mouth and throat, have perished from hunger, not being able to suck or swallow.

In a little time the constitution is contaminated by the absorption of the poison, and a series of secondary symptoms appears. In some, and especially in adult persons, dark red spots, or sometimes fungous excrecences, arise about the anus and perineum, which gradually increase and ulcerate. But the most common appearances are eruptions of a pustular character on the skin, containing, however, little fluid, and soon terminating in a dry scab, surrounded by a liquid margin, and ultimately in ulceration. In some, and especially in children, these eruptions occupy chiefly the belly, groins, and sides, and are sometimes seen on the face. The ulcers, into which they pass, usually make but small progress, not exceeding in general the point of the finger in size, and being irregular in their forms, and pretty clean, with slightly inflamed edges. In some instances, however, they have been seen to become confluent, and to unite into one large foul ulcer over a great part of the abdomen, exhaling a most intolerable and peculiar stench. In some children, indeed, the whole scalp has gangrened, and the ears have nearly fallen off. Smaller ulcers have also formed on the breast and face, covered with a purulent slough, remaining inert, without pain or inflammation, and seldom increasing in size.

In other cases, where the primary symptoms have been

moderate, and have subsided, the secondary symptoms, affecting the skin superficially, assume different shapes. The whole surface of the body, Dr. Gilchrist says, has been observed to be mottled, of a dusky copper colour, or a dirty hue, as the discolourings of the skin in this disease commonly are. Infants of the month have had a redness in the lower part of the belly, buttocks, thighs, and part of the legs, where sometimes it terminates abruptly in a ring. In some of these there was an inflammation, and a watery shining swelling of the pudenda. A more certain appearance in such subjects somewhat older are broad red patches, as large as the palm of the hand, over all the trunk, as well as the limbs, attended with inflammation. A cluster, or clusters, of small pustules come out; the skin grows dry, and peels off, leaving a new tender skin beneath; and this will happen a great many times, sometimes in one place, sometimes in another. Scabby eruptions are often met with on the scalp, forehead, inside of the thighs, groins, and parts contiguous; where frequently small hardnesses, rising just within the skin, excite a very troublesome itching. Besides the inflammation and excrescences about the fundament already noticed, other appearances of the disease present themselves on the breast, shoulders, and elsewhere, especially a sort of *herpes exedens*, or spreading tetter, healing in one part, while it breaks out in another adjoining, and leaving a great deformity of the skin, after it cicatrizes. In a few cases, an eruption of tubercles occurs upon the face, rather numerous, and in figure and size resembling the small-pox at the height, but being of a reddish colour. These are attended with great heat and tumour of the face, so as sometimes to close up the eyes. In some cases they have spread thickly over the whole body, and suppurated, not unlike the confluent small-pox, and have even proved fatal, as the swelling subsided; but in others, where not so numerous, they gradually decay, without coming to suppuration. In some persons there is a swelling of the surface, without any appearance of tubercles; in which case, the cuticle exfoliates from time to time in fine white reticulated flakes, as often as it is renewed. In other cases, tubercles arise from small bright red spots, of a more intense redness than those just mentioned, which in some places become confluent, and form a flat smooth elevation, which soon becomes of the usual colour of the skin, and sometimes slightly ulcerates. The face, too, is often affected with different kinds of eruption, sometimes alone, and sometimes together with the rest of the body.

Where the disease assumes still greater malignity, larger boils appear dispersed over the arms, shoulders, face, legs, and feet, which suppurate, and form ulcers, which penetrate to the muscular parts, laying them quite bare, and seeming even to corrode them superficially. These ulcerations are of a high florid colour, with scarcely any discharge upon their surface, except a little ichor, which renders them exquisitely tender and painful, and scarcely bearing the mildest applications. Their edges are hard and ragged, their size various, and their appearance very malignant; so that Dr. Gilchrist says, when viewed singly, they might have been mistaken for real cancers; but the number of them, the manner of their coming out, and other circumstances, soon determine the disease to which they belong.

There is one symptom, not yet particularly described, but from which the disease takes its name, which remains to be mentioned. An itchy tetter, or a sort of ring-worm, breaks out in a circular form, which either spontaneously, or from being scratched, becomes raw and excoriated, and does not scab, but continues to ooze out an ichorous hu-

mour. In a short time a fungous excrescence sprouts up, much like a raspberry or strawberry, elevated one half above the surface, and, when fully formed, appearing as if set in a socket cut in the flesh exactly to receive it. Sometimes, however, a black scab forms, crusting over the sore, except at the edges, where there is a crack or ring, like the line of separation between a mortified and a sound part, from which the same sort of ichor is constantly oozing. By degrees this crack enlarges towards the centre, and the scab, being pushed off, gives place to the fungus just described. In other cases, these spongy excrescences are preceded by a dark or grey scurf, resembling the scaly leprosy. These parts are the seat of an intense itching, and when they are excoriated by scratching or rubbing, the fungus has room to sprout up. These sores occupy every part of the body, and many of them are seen in the same subject at the same time; but the excrescences do not always sprout up, and are more commonly produced in the sores which never form a scab, than in the scabby or scaly ones. The fungus is rather indolent than tender to the touch, and its colour is not remarkably different from that of the fungus of other sores.

The siccens very rarely affects the bones, and then only by extending from the soft parts, and perhaps never attacks the large and more solid bones. In several cases, the teeth, with their sockets, have been lost, and some of the bones of the cheeks and nose have come away, and a portion of the cartilaginous separation of the nostrils has been destroyed by the disease. Several persons die in a state of hectic, from the very extensive ulcerations, before the bones could be materially affected.

*Causes of Siccens.*—This disease has been principally prevalent among the lower ranks of the people in Scotland, though not exclusively; for some families of good condition have lost their children by its attacks. The disease affects the young and adult persons equally; but persons advanced in years appear to be less liable to the infection. Children, however, and women, from their more irritable frame, are most susceptible of it.

The disease is commonly communicated by the direct conveyance of the infectious matter by some species of contact, and generally through the medium of the mouth; whence the primary symptoms appear in the mouth and throat, as before described. "It is propagated," Dr. Gilchrist observes, "by using the same spoons and knives, and wiping with the same cloth, which the infected have used, without cleansing or washing them; drinking out of the same glass or cup; smoking with the same pipe; sleeping with the infected, or in the same bed-clothes they have lain in, and handling their sores; by sucking or giving suck; saluting, or kissing, and fondling children, or feeding them in an uncleanly way."

Dr. Gilchrist adds, that it is completely proved, that the siccens is propagated chiefly by these inattentions to cleanliness, by this circumstance, that "it has never got footing among those of better fashion," nor in towns, where, except with the very lowest, greater attention to cleanliness is generally observed; and that it was unknown among the more cleanly inhabitants of the English border, while it occurred at Dumfries, and along the Scottish boundary. Another proof was deduced from the more frequent occurrence of the disease after autumn, which was thus accounted for. "A company of reapers is made up of very different people, brought together from all parts: they eat and drink promiscuously out of the same cups and dishes; and a few spoons are made to serve a good many, by putting them round from one to another. The same is done with a pipe

pipe in smoking. When the body is warm, and the pores open, the tender skin of the lips and mouth is most disposed to receive the infection, which the heat, in labouring, will render more active and apt to be communicated. A girl, who had the thrush to a great degree, at this season, spread the disease through a whole parish, where it was not formerly known."

Contagions of this sort are not usually communicable by effluvia; but it seems to be believed, by those who have witnessed the progress of fibbens, that it may be propagated without actual contact. Dr. Gilchrist says, "nor is it unlikely, that, in certain circumstances, the breath may become infectious;" implying, however, his want of positive evidence on the subject. But Dr. Paterfon asserts, that "it is perfectly ascertained, that the breath of people, labouring under the sore throat, is loaded with infection, and communicates the disease, without the contact of ulcers." Beddoes' Contributions, loc. cit.

It will be obvious, from the preceding detail of the symptoms and causes of fibbens, that it is the result of a morbid poison, operating first locally, and afterwards constitutionally, and producing phenomena exceedingly analogous to those of the venereal disease. There is also the farther analogy, as we shall see, that the cure is effected principally, if not exclusively, by mercury: whence several writers, and apparently Dr. Gilchrist among the rest, have deemed it a modification of syphilis. It was soon discovered, says this writer, "to be of the venereal kind, or the foul disease." Dr. Paterfon, however, has pointed out several circumstances which mark a difference between the two. In the first place, he observes, the venereal disease was common in Scotland long before the fibbens appeared; and he had never been able to trace the latter to any person affected with syphilis. Secondly, it is much more infectious than common syphilis, for it seldom gets into a family without infecting every person in it, and frequently spreads rapidly over a village. If the common lues were to spread in a similar manner, its progress in all large towns would be truly dreadful. Thirdly, the fibbens is a more purely cutaneous or superficial affection than the common lues, for it very rarely indeed occasions buboes, and almost never affects the large bones. And, lastly, the fibbens is much more readily cured than the ordinary form of syphilis; for a much less quantity of mercury removes blotches and extensive ulcers, than is required to cure the secondary symptoms of syphilis, contracted in the ordinary manner. Its ordinary commencement in the organs of deglutition, and its never appearing in a primary form on the genitals, nor being propagated by coition, appear also to establish a distinction between the two maladies.

*Cure of Fibbens.*—We have partly anticipated this subject in the preceding paragraph, where we have stated that mercury is found to be the specific remedy. It appears that, like syphilis, the disease is perhaps never cured by the unassisted efforts of the constitution; and that mercury, as in the other affection, does not fail to cure it, except in those deplorable cases, where, from the long continuance of the disease, hectic symptoms have come on, and the constitution is so broken down as to be unable to bear the remedy.

It seems to be a well ascertained fact, too, that, of all the preparations of mercury, the corrosive sublimate, or oxymuriate, is the best adapted for the cure of fibbens; that is, it cures it more speedily, and with equal certainty with any other mercurial preparation. This circumstance also constitutes a point of distinction between the two maladies, and may arise, according to Dr. Paterfon's suggestion, from the fibbens being a more superficial or

cutaneous affection than syphilis. Dr. Gilchrist, however, considers it better to adopt the ordinary course of mercury, though not carried to the extent of high salivation, for the purpose of insuring regularity by means of confinement, without which, he says, it often failed, and the symptoms returned, rendering another course of medicine necessary. Experience shews, he says, that the disease is proof against all slight administrations of the remedy; that it will sooner or later return with greater force, or in a worse form; and that it is only to be eradicated by a regular course of medicine, judiciously adapted to the several degrees and circumstances of the malady.

As the extensive propagation of the disease in Scotland was ascribable to the uncleanly practices which prevailed among the lower classes of the people, such as using the same utensils in eating and drinking, passing the same pipe from mouth to mouth, sleeping in the same bed, using the same towel, &c.; so the most effectual check to the progress of the malady was to be expected from a system of prevention, which consisted in adopting a more decent and cleanly proceeding. Dr. Gilchrist recommended the persons employed in harvest-work, each to carry with him a dish, cup, knife, spoon, and a cloth to wipe them with, that all the party might not eat with the same utensils, and transfer contagion to one another. He also strongly urged the impropriety of admitting that common familiarity, which every one claims by custom to kiss and fondle children, and especially to deny it to strangers, and those of low rank. By attending to these, and similar means of prevention, the disease appears to have been materially controlled, and its prevalence diminished.

SIBBIKITTIN, in *Geography*, a town of Africa, in Neola. N. lat.  $12^{\circ} 38'$ . W. long.  $11^{\circ} 35'$ .

SIBBO, a town of Sweden, in the province of Nyland; 10 miles S.W. of Borgo.

SIBBOLETH. See SHIBBOLETH.

SIBBUL, in *Geography*, a town of Africa, in the country of Barca; 25 miles W. of Augela.

SIBDA, in *Ancient Geography*, a town of Asia Minor, in Caria; one of the six towns which Alexander the Great placed in dependence on that of Halicarnassus.

SIBELLA, in *Geography*, a mountain of Calabria Ultra; 9 miles E.S.E. of St. Severina.

SIBENEN, a river of Switzerland, which runs into the Kander, 4 miles W. of Spiez.

SIBENTAAL, a town of Austria; 8 miles W. of St. Polten.

SIBERIA, or, as it is sometimes denominated, *Asiatic Russia*, is that part of the immense territory of the Russian empire, which lies to the E. of the Ural chain of mountains, by which the empire is intersected from N. to S. and thus divided into two parts, differing from each other both as to dimensions and quality. Siberia is described as a flat tract of land of considerable extent, declining imperceptibly towards the Frozen ocean, and by equally gentle gradations rising towards the south; where at last it forms a great chain of mountains, constituting the boundary of Russia on the side of China. The large portion of the habitable globe, now distinguished by the appellation of Asiatic Russia, extends from about the 37th degree E. longitude to more than  $190^{\circ}$  or  $170^{\circ}$  W. long.; and assuming the degree in this high northern latitude at 35 miles, the length may be computed at 4590 geographical miles. The greatest breadth from the cape of Severo Vostochnoi, called in some maps Taimara, to the Altaian mountains S. of the sea of Baikal, may be estimated at  $28^{\circ}$ , or 1680 geographical miles. In British miles the length, at a gross computation, may be stated

## SIBERIA.

stated at 5350, and the breadth at 1960, which extent exceeds that of Europe. The vast country of Siberia, says Mr. Tooke, contains, by calculation, upwards of  $10\frac{1}{2}$  millions of square versts, comprehending within it several kingdoms, taken by roving Kozaks (Cossacks) on their own account, and then surrendered to the tzar, who completed the conquest; at present this country consists of several of the most extensive governments. The farthest eastern boundary is that of Asia, and the seas of Kamtschatka and Ochotsk, and the northern is the Arctic ocean. On the W. the frontiers correspond with those between Asia and Europe, and the southern limits may be stated more at large in the following manner: The river Cuban, part of the Caucasian chain, and an ideal line, divide the Russian territory from Turkey and Persia. The boundary then ascends along the north of the Caspian through the steppe or desert of Issim, and the eastern shore of the river Ob, to its source in the Altaian mountains, where it meets the vast empire of China, and proceeds among that chain to the sources of the Onon, where it includes a considerable region called Daouria, extending about 200 miles in breadth, to the south of the mountains called Yablonnoy; the limit between Russia and Chinese Tartary being partly an ideal line, and partly the river Argoon, which joined with the Onon constitutes the great river Amur. Thence the boundary returns to the mountainous chain, and follows a branch of it to a promontory on the north of the mouth of the Amur.

The population of Asiatic Russia may be regarded as primitive, except a few Russian colonies recently planted; and the Techuks in that part which is opposite to America, supposed to have migrated from that continent, in their persons and customs are different from those of the Asiatic tribes. Next to the Techuks, most remotely north, are the Yukagirs, a branch of the Yakuts, and further west the Samoyedes. South of the Techuks are the Koriaks, and further south the Kamtschadales, who are a distinct people, and speak a different language. The Lamutes are a branch of the Mandshures or Tunguses, who are widely diffused between the Yenisei and Amur, and the southern tribes, ruled by a khan, conquered China in the 17th century. The Ostiaks, and other tribes of Samoyedes, have penetrated considerably to the S. between the Yenisei and the Irtysh, and are followed by various tribes of the Monguls, as the Kalmucks, Burats, &c. and by those of the Tartars or Huns, as the Teluts, Kirguses, and others. The radically distinct languages amount to seven, independently of many dialects and mixtures.

The vast extent of northern Asia was first known by the name of Sibir, or Siberia; but the appellation is gradually passing into disuse. When the Monguls established a kingdom in these northern regions, the first residence of the princes was on the river Tura, on the site of the town now called Tiumen, about 180 miles S.W. of Tobolsk; but they afterwards removed to the eastern shore of the Irtysh, and there founded the city of Isker near Tobolsk. This new residence was also called Sibir, of unknown etymology, and the name of the city passed to the Mongul principality. Although this is doubted by Coxe, Pallas says that the ruins of Sibir are still visible 23 versts from Tobolsk, and that it gave name to the rivulet Sibirka, and the whole of Siberia. When the Russians began the conquest of the country, they were unapprized of its extent; and the name of this western province was gradually diffused over the half of Asia. The principality established by the Monguls under Sheibuni in 1242 in the western part of Siberia, around Tobolsk and the river Tura, from which it has been sometimes called Tura, has been already mentioned. The actual con-

quest of Siberia commenced in the reign of Ivan Vassilievitch II., who ascended the Russian throne in 1534. Induced by the prospect of establishing a traffic for Siberian furs, he determined to undertake the conquest of the country, and in 1558 added to his titles that of lord of Sibir, or Siberia. Yarmak, a Cossack chief, being driven, by the Russian conquests in the south, to take refuge, with 6000 or 7000 of his followers, near the river Kama, afterwards marched down the Ural chain, defeated the Tartar Kutchun, khan of Sibir, and pressed forwards to the Tobol and the Irtysh, and also to the Oby, and in this astonishing expedition, subjugated Tartars, Vogules, and Ostiaks. Finding it impossible to maintain and complete his conquests with his small army, he surrendered them in 1581, by a formal capitulation, to the tzar Ivan Vassilievitch, who nobly rewarded his magnanimity and exertions. This conqueror of Siberia, however, did not live to witness the full accomplishment of this enterprise. He died in 1584; and after his death the discovery and conquests which he had made were prosecuted by regiments of Donskoi Cossacks, sent thither for that purpose, as far as the eastern ocean and the mountains of China; and in the middle of the 17th century this whole part of the world had become a Russian province. A person, whose name was Cyprian, was appointed first archbishop of Sibir in 1621, and at Tobolsk, where he resided, he drew up a narrative of the conquest. About the middle of the 17th century the Russians had extended east as far as the river Amur; but Kamtschatka was not finally reduced till the year 1711. Behring and other navigators afterwards proceeded to discover the other extreme parts of Asia. In his first voyage of 1728, Behring coasted the eastern shore of Siberia as high as latitude  $67^{\circ} 18'$ , but his important discoveries were made during his voyage of 1741. The Aleutian isles were visited in 1745; and in the reign of the empress Catharine II. other important discoveries followed, which were completed by captain Cook. In the south the Mongul kingdom of Kazan was subdued in 1552, and that of Astrakhan in 1554, and the Russian monarchy extended to the Caspian sea. In 1727, after previous conflicts, the Russian limits were continued westward from the source of the Argoon to the mountain Sabyntaban, near the conflux of two rivers with the Yenisei; the boundary being thus ascertained between the Russians and the Monguls subject to China. The trade with China has been conducted at Zuruchaitu, on the river Argoon, N. lat.  $50^{\circ}$ . E. long.  $337^{\circ}$ , and at Kiachta, about 90 miles S. of the sea of Baikal, N. lat.  $51^{\circ}$ . E. long.  $106^{\circ}$ . This boundary between two states is the most extensive on the globe, reaching from about the 65th to the 145th degree of longitude;  $80^{\circ}$  (lat.  $50^{\circ}$ ) yielding, by the allowance of 39 geographical miles to a degree, 3120 miles.

The most curious antiquities in Siberia seem to be the stone tombs which abound on some steppes, particularly near the river Yenisei, representing in rude sculpture human faces, camels, horsemen with lances, and other objects. Here are also found, besides human bones, those of horses and oxen, with fragments of pottery and ornaments of dress. The most singular ancient monument in Siberia is found on the river Abakan, not far from Tomsk, being a large tomb with rude figures.

The religion of the Greek church, which is professed by the Russians, has made no great progress in their Asiatic dominions. Many of the Tartar tribes in the S.W. are Mahometans, and others are votaries of the superstition of Dalai Lama. But the religious sentiments of the Schamanians are the most prevalent; particularly among the Tartars, Finns, Samoyedes, Ostiaks, Mandshurs, Burats, and Tunguses;

## SIBERIA.

guses; and they have been adopted by the Koriaks, Tchuks, and people of the eastern isles. On the eastern coast of the sea of Baikal is the rock of the Schamans, an idol of a peculiar shape: whilst the Schamanians admit one chief infernal deity and his subalterns, authors of evil, they also believe in one supreme uncreated beneficent being, who commits the management of the universe to inferior deities, and they delegate portions of it to subaltern spirits. See SCHAMANS.

The archiepiscopal see of Tobolsk is the metropolitan of Russian Asia in the north, and that of Astrakhan in the south. There is another see, that of Irkutsk and Nerzhinsk, and some others of more recent origin.

Siberia is divided into two great governments, those of Tobolsk in the west, and Irkutsk in the east. The smaller provinces are Kolyvan, Nerzhinsk, Yakutsk, and Ochotsk. In the S.W. is the government of Caucasus, with one or two other divisions, blending Europe and Asia.

The population of Siberia cannot be computed at above  $3\frac{1}{4}$  millions. The political importance and relations of this part of the Russian empire principally relate to China and Japan. The manners and customs of Asiatic Russia vary with the numerous tribes by whom it is peopled. The Tartars are the most numerous; next to these in importance are the Monguls, one tribe of whom, *viz.* the Kalmucks, are found to the W. of the Caspian, while the others, called Burats, Torgats, &c. are chiefly round the sea of Baikal. Further to the east are the Mandshurs or Tunguses. See these denominations respectively.

The languages of all the original nations of Asiatic Russia are radically different; and among the Tunguses, Monguls, and Tartars, there are some traces of literature, and not a few MSS. in their several languages.

The principal city of Asiatic Russia is Astrakhan, which see. Azof (which see) derives its importance chiefly from its being a fortified port. The chief towns on the Asiatic side of the Volga, are Samara and Stauropol. At the mouth of the river Ural, or Jaik, stands Gurief; but the chief place after Astrakhan is Orenburgh, founded in the year 1740, and the seat of a considerable trade with the tribes on the E. of the Caspian. Beyond the Uralian chain the first city that occurs is Tobolsk; which see. Kolyvan is a town of some consequence on the river Ob, having in its vicinity some silver mines of considerable produce, and north to this is Tomsk. Farther to the E. the towns become of less consequence. On the river Yenisei is a small town of the same name, and another called Sayansk. On the river Angara stands Irkutsk, supposed to contain 12,000 inhabitants, the chief mart of the commerce between Russia and China, and the seat of supreme jurisdiction over eastern Siberia. On the wide and frozen Lena stands Yakutsk; which see.

The chief commerce of this part of the Russian empire consists in fables and other valuable furs, for which the Chinese return tea, silk, and nankeen. That with the Kirguses consists in exchanging Russian woollen cloths, iron, and household articles, for horses, cattle, sheep, and beautiful sheepskins. On the Black sea there is some commerce with Turkey, the exports being furs, kaviar, iron, linen, &c. and the imports wine, fruit, coffee, silks, rice. In the trade on the Caspian the exports are the same, and the return chiefly silk. The principal Russian harbours are Astrakhan, Gurief, and Kishiar, near the mouth of the Terek, but the best haven is Baku, belonging to the Persians. The Tartars, on the east of the Caspian, bring the products of their country and of Bucharia, as cotton-yarn, furs, stuffs, hides, and rhubarb; but the chief article is raw silk from Shirvan and Ghilan, on the W. of the Caspian.

In Asiatic Russia the climate extends from the vine at the

bottom of the Caucasus, to the solitary lichen on the rocks of the Arctic ocean. Through the greater part of Siberia, the most southern frontier being about  $50^{\circ}$ , and the northern ascending to  $78^{\circ}$ , the general climate may be considered rather as frigid than temperate; being in three quarters of the country on a level with that of Norway and Lapland, untempered by the gales of the Atlantic. To the S. of the sea of Baikal, the climate corresponds to that of Berlin, and the N. of Germany. The chains of high mountains, which form the southern boundary of these provinces, contribute also to increase the cold; so that the sea of Baikal is commonly entirely frozen from December till May. The finest climate in these eastern parts is that of Daouria, or the province around Nerzhinsk: and the numerous towns on the Amur evince the great superiority of what is called Chinese Tartary, which is comparatively a fertile and temperate region. The change of the seasons is very rapid; the long winter is almost instantaneously succeeded by a warm spring; and the quickness and luxuriance of the vegetation exceed description.

The greater part of Siberia, that is, the middle and southern latitudes of it, as far as the river Lena, is extremely fertile, and fit for every kind of produce; but the northern and eastern parts, being encumbered with wood, are destitute of this advantage, being unfit both for pasturage and culture. The whole of this part, as far as the 60th degree of N. latitude, and to the Frozen ocean, is full of bogs and morasses covered with moss, which would be absolutely impassable, if the ice, which never thaws deeper than seven inches, did not remain entire beneath it. In the central parts vegetation is checked by the severe cold of so wide a continent. Towards the S. there are vast forests of pine, fir, larch, and other trees, among which is a kind of mulberry, which might thrive in many climates that are now destitute of it. The sublime scenes around the sea of Baikal are agreeably contrasted with the marks of human industry, the cultivated field and the garden. Many parts of Siberia are totally incapable of agriculture; but in the southern and western districts the soil is remarkably fertile. North of Kolyvan barley generally yields more than twelve-fold, and oats commonly twenty-fold. Exclusive of winter wheat, most of the usual European grains prosper in southern Siberia. In some parts flax grows wild, and hemp is prepared from the nettle. Woad is found in Siberia, and saffron near the Caucasus. The best rhubarb abounds on the banks of the Ural or Jaik, in the southern districts watered by the Yenisei, and in the mountains of Daouria. But it is not possible that agriculture should flourish while the peasantry are slaves, and sold with the soil. Nevertheless, an intelligent traveller was surprised at the abundance of buck-wheat, rye, barley, oats, and other grain which he observed to the S. of Tobolsk; where the cattle were also very numerous, and in the winter fed with hay. The large garden strawberry, called hautbois, is found wild in the territory of Irkutsk; and on the Altai mountains the red currant attains the size of a common cherry, ripening in large bunches of excellent flavour. Near the Volga and the Ural are excellent melons of various kinds.

Some of the largest rivers of Asia belong to the Russian empire: such are the Ob, of 1900 British miles in course; the Yenisei, about 1750; and Lena, 1570. To these we may add the Irtysh, the Angara, the Selenga, the Yaik, &c. The lakes of this country are numerous. The most considerable in the north of Siberia is that of Piazmsko; that of Baikal, described under that article; a large lake between the rivers Ob and the Irtysh, 170 miles long, divided by an island into two parts, called the lakes of Tchang and Soumi.

In this quarter there are many smaller lakes, and others to the N. of the Caspian, some of which are salt, particularly that of Bogdo. To these we may add the Altan Nor, or golden lake, and the lake of Altyn, called by the Russians Teletako. The mountains are the Uralian, the Altaian, Bogdo Alim, or the Almighty mountain, Sinnaia-Sepka, Schlangenberg, which is the richest in minerals, the Sayansk mountains, the mountains of Nerzhinsk or Russian Daouria, the chain of Stanvooi or mountains of Oehotik, and Caucasus. For the steppes of Russia, see STEPPE.

Siberia has hitherto been found to possess scarcely any genera of plants; and even all the species of any considerable importance, are those trees which are common to it with the north of Europe. Under the head of the zoology of Asiatic Russia, we may enumerate the rein-deer, which performs the offices of the horse, the cow, and the sheep; the dogs of Kamtschatka, which are used for carriage; the horse, which is found wild, a species of ass, the urus or bison, the argali or wild sheep, the ibex or rock-goat, large stags, the musk or civet, and wild boar; wolves, foxes, and bears; the sable, several kinds of hares, the castor or beaver, the walrus, and the common seal. But it would be superfluous to enlarge. Siberia is so rich in zoology and botany, that, as Mr. Pennant observes, even the discovery of America has scarcely imparted a greater number of objects to the naturalist. The mineralogy of Siberia is equally fertile, and displays many singular and interesting objects. The chief gold mines of Siberia are those of Catherinburg or Ekatherinburg, on the E. of the Uralian mountains, about N. lat. 57°: the mines of Nerzhinsk, discovered in 1704, are principally of lead, mixed with silver and gold; and those of Kolyvan, chiefly in the Schlangenberg, or mountain of serpents, so called by the Germans, began to be wrought in 1748. The gold mines of Berefof are the chief in the empire; those of Kolyvan and Nerzhinsk being denominated silver mines. Besides the copper mines in the Uralian mountains, there are some in those of Altai. But the iron mines of Russia are of the most solid and lasting importance, particularly those which supply the numerous founderies of the Uralian mountains. Rock-salt is chiefly found near the Ilek, not far from Orenburg. Coal is scarcely known; but sulphur, alum, sal ammoniac, vitriol, nitre and natron, are abundant. Siberia possesses a variety of gems, particularly in the mountain Adunskollo, near the river Argoon, in the province of Nerzhinsk or Daouria. Common topazes are found here, and also the jacinth. The kind of jade called mother of emerald is a Siberian product; and beryl or aqua marinus is found in Adunskollo, and in greater perfection in the gem mines of Mourmintsy, near Catherinburg, along with the chrysolite. Red garnets abound near the sea of Baikal. The ruby-coloured fchorl has been discovered in the Uralian mountains. The green felpar of Siberia is a beautiful stone, and carved by the Russians into a variety of ornaments. The Daourian mountains, between the Onon and the Argoon, afford elegant onyx. The beautiful stones called the hair of Venus and Thetis, being limpid rock crystals containing capillary fchorl, red or green, are found near Catherinburg. The alliance stone consists of a greyish porphyry, united, as if glued together, with transparent quartz. Great quantities of malachite have also been found in the Uralian mountains; one piece of which is said to have weighed 107 pounds, or 3852 pounds. Siberia affords beautiful red and green jaspers; and lapis lazuli is found near Baikal. The Uralian chain presents fine white marble; and in the numerous primitive ranges there are many varieties of granite and porphyry. The chief mineral waters of Russia are those of Kamtschatka.

The islands belonging to Asiatic Russia may be distributed into the Aleutian, Andrenovian, and Kurilian groups, with the Fox isles, which extend to the promontory of Alaska in North America. See these articles respectively. For further particulars respecting Siberia or Asiatic Russia, see RUSSIA. See also COXE's Russian Discoveries; TOOKE's Russ. Emp.; and PINKERTON's Geog. vol. ii.

SIBERIAN KOZAKS, or *Cossacks*, a branch of the Donskoi Cossacks, who, intiguated by a disposition to roaming and pillage, in the 16th century, abandoned their habitations on the Don, in order to plunder the countries lying eastward. In order to restrain their progress, Ivan Vassilievitch II., who sat upon the Russian throne, assembled, in the year 1577, a considerable army, and got together a fleet of ships to chastise these audacious robbers. These hordes, intimidated by these hostile preparations, dispersed and fled into the neighbouring regions. See the preceding article.

SIBERIAN Barley, in *Agriculture*, a hardy sort of grain of the barley kind. See BARLEY.

SIBERIAN Oat, an useful sort of hardy oat brought from that country. See OAT.

It has been found by some as much superior to the common black oat as the Poland sort is to others. It has the advantages of being capable of being sown with safety in December, and of being fit to cut as soon or sooner than early peas; the produce is greater than the usual sorts; and rain, instead of injuring, rather improves the colour, which is of the pied kind. The kernel is plump and large, and the straw is said to make excellent fodder for live-stock of the neat cattle kind.

SIBIDOOLOO, in *Geography*, a town of Africa, in the state of Manding, the government of which is a republic, or rather an oligarchy; 40 miles N.E. of Kamalia.

SIBIL-EL-MULSIH, a town of Arabia, in the province of Hedsjas; 120 miles N.N.W. of Mecca.

SIBILI, a town of Africa, in the kingdom of Bambara; 25 miles N.E. of Segou.

SIBILIAKOVA, a town of Russia, in the government of Tobolsk, on the Irtysh; 28 miles N. of Tara.

SIBIRIXOA, a town of New Mexico, in the province of Cinaloa; 45 miles N.N.W. of Cinaloa.

SIBINBAS, a town of Hindooistan, in Bengal; 10 miles E.N.E. of Kishenagur. N. lat. 23° 25'. E. long. 88° 50'.

SIBOCKOO, a town on the E. coast of the island of Borneo. N. lat. 4° 24'. E. long. 117° 12'.

SIBOURNE, a town of France, in the department of the Lower Pyrenées, on a small river opposite to St. Jean de Luz.

SIBRAIM, or SABARIM, in *Ancient Geography*, a place which terminated the land of promise towards the north. Ezekiel says (xlvi. 16.) that this city was between the confines of Hamoth and Damascus, probably the same which Abulfeda calls Houverin, a village of the country of Ems, or Hamoth, S.E. of that city.

SIBSIB, in *Zoology*, an animal of the empire of Morocco, abounding in the mountains of the province of Sufe; of an intermediate species between the cat and the squirrel; somewhat similar to the ichneumon in form, but not half its size: it inhabits the Atlas, and lives in holes, among the stones and caverns of the mountains; it has brown hair, and a beautiful tail, resembling that of a squirrel, about the length of its body. The Shelluks and Arabs eat this animal, and consider it a delicacy. This is the only animal which the Mahometans torment before its death, which they do by taking hold of its hind-legs, and rubbing it on a stone, or flat

flat surface, for a few minutes, which operation causes the animal to scream out. They then cut its throat, according to the Mahometan custom. In taste it is said to resemble a rabbit; but friction, as they pretend, is necessary to render it tender and palatable.

SIBTHORP, JOHN, in *Biography*, an eminent botanist and traveller, was the youngest son of Dr. Humphrey Sibthorp, professor of botany at Oxford, where the subject of the present article was born, October 28, 1758. He received the first rudiments of his education at Magdalen school, from whence he was removed to the school at Lincoln. In due time he entered at Lincoln college, Oxford; but upon obtaining the Radcliffe travelling fellowship, he became a member of University college. Being intended for the medical profession, he was necessarily sent to Edinburgh, to complete that branch of his education; but he took the degree of doctor of physic in his own university. The taste he had early imbibed for natural history, especially botany, was cultivated at Edinburgh, and indulged in a tour to the Highlands of Scotland. After his return from thence, he visited France and Switzerland, spending a considerable time at Montpellier, where he formed an intimacy with the amiable Broussonet, (see PAPHYRIUS,) collected many plants of that country, and communicated to the Academie des Sciences of Montpellier, of which he became a member, an account of his numerous botanical discoveries in the neighbourhood. The death of an elder brother of his father, by which a considerable estate devolved on the latter, occasioned Dr. J. Sibthorp to return to England in 1783, when, on his father's resignation, he was appointed to the botanical professorship. For this his Oxford degree of M.D. was necessary. (See SHERARD, and SIBTHORPIA.) It was perhaps the last service he expected from it, for he was a favourite son, and had besides an ample independency of his own in prospect, from the estate of his mother, who was his father's second wife. These expectations, and his academical appointments, though they released him from the calls of his profession, only riveted more firmly his ardent attachment to botany; his passion for which became, by those appointments, a duty; nor was he ever, to his last hour, disposed to shrink from the task he had undertaken, or to prefer any relaxation, or any indulgence, to this laborious pursuit.

During the stay of professor J. Sibthorp at London, in the winter of 1783, the museum and library of the celebrated Linnæus were sold, by private contract, to the writer of this article. The professor was commendably desirous of adding to great a treasure to the collections, already famous, at Oxford; but the acquisition depended on a resolute and decisive step, which was already taken, and not on any management or negotiation, to which the person entrusted with the sale was superior. This competition occasioned no interruption in the friendship, just then formed, between the parties concerned, which continued increasing during their joint lives.

Dr. Sibthorp passed a portion of the year 1784 at Göttingen, where he projected his first tour to Greece; the botanical investigation of which celebrated country, and especially the determination of the plants mentioned by its classical authors, had, for some time past, become the leading object of his pursuits. He first visited the principal seats of learning in Germany, and surveyed some of its mountains and forests; but it was impossible to quit this part of the world without a considerable stay at Vienna. There he cultivated the friendship of the two professors Jacquin, father and son; studied with peculiar care the celebrated manuscript of Dioscorides, which has so long been preserved in the imperial library; and procured a most excellent draughts-

man, Mr. Ferdinand Bauer, to be the companion of his expedition. On the 6th of March, 1786, they set out together from Vienna, and passed through Carniola to Trieste, Venice, Bologna, Florence, Rome, and Naples, examining every thing that was curious, and keeping an exact record of their botanical observations. After viewing the celebrated environs of Naples, they sailed from thence early in May, and touching at Messina, as well as at the isle of Milo, they proceeded to Crete. Here, in the month of June, our botanical adventurers were welcomed by Flora in her gayest attire. The snowy covering of the Sphaciote mountains was withdrawing, and a tribe of lovely little blossoms were just peeping through the veil.

Having narrowly escaped shipwreck, in returning to Milo by one of the country vessels, Dr. Sibthorp and Mr. Bauer touched successively at several islands of the Archipelago, visited Athens, and remained for a while at Smyrna. Here they traced the steps of Sherard and Hasselquist, proceeded by land to Burfa, climbed the Bithynian Olympus, and at length reached Constantinople, where they spent the ensuing winter, in the course of which Dr. Sibthorp devoted himself to the study of modern Greek. In a botanical excursion to Belgrad, on the 17th of February, 1787, and another to Bujekderi, March 5, the plants found in flower were almost entirely the same as are met with, at the same season, in England. Dr. Sibthorp's residence at Constantinople, or in the neighbouring isle of Karki, proved favourable to his investigations of the fishes and birds of those regions, by which he was enabled to throw much light on the writings of ancient naturalists.

On the 14th of March, 1787, having joined company with captain Emery and Mr. Hawkins, Dr. Sibthorp and his draughtsman sailed from Constantinople in a Venetian merchant-ship for Cyprus, taking the islands of Mytilene, Scio, Cos, and Rhodes, and touching at the coast of Asia Minor, in their way. A stay of five weeks at Cyprus enabled Dr. Sibthorp to draw up a *Fauna* and *Flora* of that island. The former consists of 18 *Mammalia*, 85 Birds, 19 *Amphibia*, and 100 Fishes; the latter comprehends 616 species of plants. The particular stations, domestic and medical uses, and reputed qualities of these last, are amply recorded; and the vernacular names of the animals, as well as of the economical plants, are subjoined. The same method is pursued, in a subsequent part of this journal, respecting the plants and animals of Greece, with every thing that could be collected relative to the medicine, agriculture, and domestic economy of that country and the circumjacent isles. The illustration of the writings of Dioscorides, in particular, was Dr. Sibthorp's chief object. The names and reputed virtues of several plants, recorded by that ancient writer, and still traditionally retained by the Athenian shepherds, served occasionally to elucidate, or to confirm, their synonymy. The first sketch of the *Flora Græca* comprises about 850 plants. "This," says the author, "may be considered as containing only the plants observed by me in the environs of Athens, on the snowy heights of the Grecian Alp Parnassus, on the steep precipices of Delphus, the empurpled mountain of Hymettus, the Pentele, the lower hills about the Piræus, the olive grounds about Athens, and the fertile plains of Bœotia. The future botanist, who shall examine this country with more leisure, and at a more favourable season of the year, before the summer sun has scorched up the spring plants, may make a considerable addition to this list. My intention was to have travelled by land through Greece: but the disturbed state of this country, the eve of a Russian war, the rebellion of its bashaws, and the plague at Larissa, rendered my project impracticable." Of the *Mammalia* of Greece,

## SIBTHORP.

Greece, 37 are enumerated, with their modern names, 25 reptiles and 82 birds. All these catalogues were greatly augmented by subsequent observations, inasmuch that the number of species, collected from an investigation of all Dr. Sibthorp's manuscripts and specimens for the materials of the *Prodromus Flora Græcæ*, amounts to about 3000.

We shall not particularly trace our traveller's steps through Greece, or the various islands of the Archipelago. His health, which suffered from the confinement of a ship, and the heat of the weather, was restored at Athens, where he arrived on the 19th of June, 1787. From thence he prosecuted his journeys in various directions, and with various successes. The ascent of mount Delphus, or Delphi, in Negropont, in a storm of wind and rain, on the 3d of August, was one of his most laborious, if not perilous, adventures; but his botanical harvest was abundant. With regard to scenery, mount Athos, which he visited a week after, seems to have made most impression on his mind. This spot also greatly enriched his collection of rare plants. From hence he proceeded to Theſſalonica, Corinth, and Patras, at which last place he embarked with Mr. Bauer, on board an English vessel, for Bristol, on the 24th of September. After a tedious and stormy voyage, they arrived in England the first week in December.

The constitution of Dr. Sibthorp, never very robust, had suffered materially from the hardships and exertions of his journey. But his native air, and the learned leisure of the university, gradually recruited his strength. The duties of his professorship were rather a recreation than a toil. The superintendance of his exquisite draughtsman, now engaged in making finished drawings of the Greek animals, as well as plants; and his occasional visits to the Linnæan and Banksian herbariums, for the removal of his difficulties; all together filled up his leisure hours. He was every where welcomed and admired for his ardour, his talents, and his acquisitions. His merits procured an augmentation of his stipend, with the rank of a Regius professor; both which advantages were, at the same time, conferred on his brother professor at Cambridge. He became a fellow of the Royal Society in 1789, and was among the first members of the Linnæan Society, founded in 1788. In the spring of the year last mentioned, the writer of this, with sir Joseph Banks and Mr. Dryander, passed a week at Oxford, which was devoted to a critical survey of the professor's Grecian acquisitions; nor was the honey of mount Hymettus, or the wine of Cyprus, wanting at this truly attic entertainment. But the greater these acquisitions, the less was their possessor satisfied with them. No one knew, so well as himself, how much was wanting to the perfection of his undertaking, nor could any other person so well remedy these defects. Though he was placed, a few years after his return, in very affluent circumstances; and though his necessary attention to his landed property, and to agricultural pursuits, of which he was passionately fond, might well have turned him, in some measure, aside from his botanical labours; he steadily kept in view the great object of his life, to which he finally sacrificed life itself. No name has a fairer claim to botanical immortality, among the martyrs of the science, than that of Sibthorp.

On the 20th of March, 1794, Dr. Sibthorp set out from London, on his second tour to Greece. He travelled to Constantinople in the train of Mr. Liston, ambassador to the Porte, and was attended by Francis Borone, of whom an account may be seen at the end of the article *RUTACEÆ*, as a botanical assistant. They reached Constantinople on the 19th of May, not without Dr. Sibthorp's having suffered much from the fatigues of the journey, which had brought on a

bilious fever. He soon recovered his health at Constantinople, where he was joined by his friend Mr. Hawkins from Crete. Towards the end of August they made an excursion into Bithynia, and climbed to the summit of Olympus, from whence they brought a fresh botanical harvest. Dr. Sibthorp discovered at Fanâr an aged Greek botanist, Dr. Dimitri Argyrami, who had known the Danish traveller Forskall, and who was possessed of some works of Linnæus.

Recovered health, and the accession of his friend's company, caused Dr. Sibthorp to set out with alacrity on his voyage to Greece, on the 9th of September. Passing down the Hellepont, on the 13th, with a light but favourable breeze, they anchored at Koum Cale, in the Troad, spent two days in examining the plains of Troy, and then proceeded to the isles of Imbros and Lemnos. On the 25th they anchored at mount Athos, and passed ten days in examining some of the convents and hermitages, with the romantic scenery, and botanical rarities, of that singular spot, on all which Dr. Sibthorp descants at length, with great delight, in his journal. Their departure was, for some time, prevented, by a few Barbary pirates hovering on the coast, whom these monks, unlike the priests of the Athenian Bacchus, were not potent or valiant enough to defeat, or to turn into dolphins. Our voyagers sailed on the 5th of October, and on the 7th landed at Skiatho. From hence, on the 11th, they proceeded down the strait of Negropont, and on the 13th passed under the bridge of five arches, which connects that island with the main land of Greece. On the 15th, at noon, they entered the harbour of the Pyræus, and proceeded to Athens, where the four succeeding weeks were employed in collecting information relative to the present state of the government, the manufactures, and the domestic economy of that celebrated spot. Here Dr. Sibthorp lost his assistant Borone, who perished by an accidental fall from a window, in his sleep, on or about the 20th of October.

November 16th, Dr. Sibthorp and Mr. Hawkins left Athens by the ancient Eleusinian way, while the classical streams of the Cephissus, the heights of Helicon and Parnassus lay before them. They proceeded to Patras and to Zante, where they arrived in the middle of December, enriched with a large collection of seeds, the only botanical tribute that could, at this season, be collected from those famous mountains. An apothecary at Zante furnished Dr. Sibthorp with an ample and splendid herbarium, of the plants of that island, with their modern Greek names; nor did the winter pass unprofitably or unpleasantly in this sequestered spot; where neither agreeable society, nor copious information relative to our learned travellers' various objects, was wanting. The season was sufficiently favourable in the middle of February, 1795, to allow them to visit the Morea, of which peninsula they made the complete circuit in somewhat more than two months. The Violet and Primrose welcomed them in the plains of Arcadia; and the *Narcissus Tazzetta*, which Dr. Sibthorp was disposed to think the true poetic Narcissus, decorated in profusion the banks of the Alpheus. The barbarian horde, under whose escort they were obliged to travel, had taste enough to collect nosegays of these flowers. The oaks of the Arcadian mountains presented them with the true ancient Mistletoe, *Loranthus europæus*, which still serves to make birdlime; whilst our Mistletoe, *Viscum album*, in Greece grows only on the Silver Fir. May not this circumstance account for the old preference of such Mistletoe as grows on the oak, among the ancient Britons, and consequently help us to trace the origin of their superstition to Greece? (See *DRUIDS*.) The Jay, still called by its ancient

## SIBTHORP.

ancient name *Κισσος*, which is generally taken for the Magpie, was screaming among these oaks: and the Water Ouzel, *Sturnus Cinclus*, flying along the rocky sides of the alpine rivulets of Arcadia, presented itself to Dr. Sibthorp's recollection, as probably the White Blackbird, which Aristotle says is peculiar to the neighbourhood of mount Cyllene. In vain did our classical travellers look for the beauty of Arcadian shepherdesses, or listen for the pipe of the sylvan swain. Figures emaciated, and features furrowed, with poverty, labour and care, were all that they met with. The vermin of the Pacha's court, with other vermin, who presume to call themselves Christian bishops, and whose places are all bought of the Turks, devour the substance of these poor people, and drive many of them to a precarious and predatory life among the mountains.

Proceeding to Argos, and thence to Mycena, the travellers were highly gratified by finding, on the gate of the latter, those ancient lions, which Pausanias describes as the work of the Cyclops; and near it the reputed tomb of Agamemnon, a circular building, formed of immense masses of stone, placed with such geometrical precision, though without mortar, that not one had given way. That which forms the portal is described by Dr. Sibthorp as the largest stone he ever saw employed in any edifice. A number of fragments of vases, like those commonly called Etruscan, lay among the ruins of Mycena. At Hermione, now called Castri, in the Argolic peninsula, famous for the purple dye anciently prepared there, a vast pile of the shells from which that dye was obtained, and still denominated *Porphyri*, served to ascertain the species, which is *Murex Trunculus* of Linnæus, figured by Fabius Columna in his rare and learned work, *de Purpurâ*, under the name of *Purpura nostras violacea*. (See PURPLE FISH.) From this place Dr. Sibthorp and his friend intended to have coasted along the bay of Argos in a boat, but the sea was then infested with pirates, which obliged them to give up that project, and to return by land to Argos, whence they proceeded to Corinth, Patras, and by way of Elis to Pyrgos. Here they obtained another escort from Said Aga, to whose protection they had before been indebted, and safely reached Calamata, on the gulf of Corone, where they were detained by the celebration of Easter, on the 12th of April, amid a profusion of sky-rockets and crackers. Proceeding in a boat along the barren and craggy shore, covered with bushy and prickly *Euphorbia*, they reached Cardamoula. Here the Greeks are tolerably free from the tyranny of the Turks, and their persons and demeanour exhibit less marks of degeneracy. Panagioté, a popular character, nephew of the Cherife, came down, with a train of followers, to welcome the strangers, and conducted them to his tower-like castle, where a narrow entrance, and dark winding stair case, led to a chamber, whose thick walls and narrow loop-holes seemed well prepared for defence. The country of Maina, though governed by a Bey, is under the controul of eight subordinate, but partly independent, native chiefs, who, like our old feudal lords, often make war on each other, when they bring not only men but women into the field. No Turk is allowed to live in this district. The land is extremely hilly, and easily defended. Taygetus, the highest mountain in the Morea, and almost rivalling Pariallus, was ascended by our adventurous travellers; but the quantity of snow, and the great distance, prevented their reaching the summit. Panagioté and fifty of his followers accompanied them, and he displayed his botanical knowledge by shewing Dr. Sibthorp darnel, still called *αἴρα*, among the corn, which he said occasioned dizziness; and a wonderful root, the top of which is used as an emetic, the bottom as a purge. This

proved *Euphorbia Apios*, to which the very same properties are attributed by Dioscorides.

From Cardamoula the travellers were escorted by the dependants of this hospitable Grecian chief, along a precipitous road, to Mittra, where they had the unexpected pleasure of meeting a party of their English friends, in the garb of Tartars, with whom they explored the site of ancient Sparta. After returning to Calamata, and surveying from the summit of a neighbouring precipice the ruins of Mellenia, with the rich plains watered by the Paniscus, and bounded by the hills of Laconia, Dr. Sibthorp and Mr. Hawkins halted to Corone, where a Venetian vessel waited to convey them to Zante, which place they reached on the 29th of April. Here Dr. Sibthorp parted from the faithful companion of his tour, whom he was destined never to see again, but in whose friendship he safely confided in his last hours. Mr. Hawkins returned to Greece; while the subject of our memoir, leaving Zante on the 1st of May, experienced a most tedious voyage of twenty-four days to Otranto, though five days are the most usual time for that passage. He touched at the island of Cephalonia, and next at Preverfa, on the Grecian shore, where being detained by a contrary wind, he employed the 7th of May in visiting the ruins of Nicopolis. The weather was unfavourable, and Dr. Sibthorp here caught a severe cold, from which he never recovered. It seems to have proved the exciting cause of that disease, which had long been latent in the mesenteric and pulmonary glands, and which terminated in a consumption. Being obliged by the weather to put in at the little island of Fanno, May 11th, the violent north-west wind "continued," as he too expressively says in his journal, "to nurse his cough and fever." He was confined to his bed, in a miserable hovel, to which, after frequent attempts to sail, he was driven back six times by the unfavourable wind. At length, the vessel was enabled to cast anchor in the port of Otranto on the 24th of May. Here he was obliged to submit to a quarantine of three weeks, part of which, indeed, was allowed to be spent in proceeding to Ancona. From thence he passed through Germany and Holland to England. Of the precise time of his arrival we find no mention. It was in the autumn of 1795, and his few succeeding months were chiefly marked by the progress of an unconquerable disease, for which the climates of Devonshire and Bath were, as usual, resorted to in vain. He died at Bath, February 8th, 1796, in the thirty-eighth year of his age, and lies interred in the abbey church, where his executors have erected a neat monument to his memory.

We have now to record the posthumous benefits which Dr. Sibthorp has rendered to his beloved science, and which are sufficient to rank him amongst its most illustrious patrons. By his will, dated Ashburton, January 12, 1796, he gives a freehold estate in Oxfordshire to the university of Oxford, for the purpose of first publishing his *Flora Græca*, in 10 folio volumes, with 100 coloured plates in each, and a *Prodromus* of the same work, in 8vo. without plates. His executors, the honourable Thomas Wenman, John Hawkins and Thomas Platt, esqrs., were to appoint a sufficiently competent editor of these works, to whom the manuscripts, drawings, and specimens, were to be confided. They fixed upon the writer of the present article, who has now nearly completed the *Prodromus*, and the second volume of the *Flora*. The plan of the former was drawn out by Dr. Sibthorp, but nothing of the latter, except the figures, was prepared, nor any botanical characters or descriptions whatever. The final determination of the species, the distinctions of such as were new, and all critical remarks, have fallen to the lot of the editor, who has also revised the re-

ferences to Dioscorides, and, with Mr. Hawkins's help, corrected the modern Greek names, which last were necessarily taken down but incompletely, from many illiterate and imperfect authorities, on the spot. When these publications are finished, the annual sum of 200*l.* is to be paid to a professor of rural economy, who is, under certain limitations, to be the Sherardian professor of botany, and who is, very properly, obliged to read lectures, that the appointment may not become a reproach, instead of an advantage, to the university. The remainder of the rents of the estate above mentioned is destined to purchase books for the professor; and the whole of the testator's collections, with his drawings, and books of "Natural History, Botany, and Agriculture," are given to the university. This bequest rivals the munificence of Sherard and of Sloane, in the service of natural science, and has only been exceeded by that of the late Mr. Robertson of Stockwell, whose ill-made will was set aside by the common law of the land.

The only work which professor John Sibthorp published in his life-time is a *Flora Oxoniensis*, in one volume 8vo. printed in 1794. It has the merit of being entirely founded on his own personal observation. The species enumerated amount to 1200, all gathered by himself, and disposed according to the Linnæan system, with the alterations of Thunberg, which were then new, but which are now not admitted as improvements. The adoption, though imperfect, of Hedwig's genera of Mosses in this *Flora*, must be esteemed a more fortunate measure. S.

SIBTHORPIA, in *Botany*, was so called by Linnæus, in compliment to Dr. Humphrey Sibthorp, for about forty years professor of botany at Oxford, and the immediate successor of Dillenius. He is said to have delivered but a single lecture in all that time, which was not a successful one, nor do we know of his having enriched the science with any publication. A short letter from this gentleman, announcing the death of his predecessor, is extant among the *Epistole ad Hallerum*. In this he modestly expresses a wish that he were equal to the task before him. However imperfect his claims to botanical celebrity, his son has conferred more honour on the above name than either of them could derive from it; see the preceding article.—Linn. Gen. 320. Schreb. 418. Willd. Sp. Pl. v. 3. 340. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 667. Prodr. Fl. Græc. Sibth. v. 1. 439. Ait. Hort. Kew. v. 4. 51. Juss. 99. Lamarck Illustr. t. 535. Gært. t. 55.—Clas and order, *Didymia Angiosperma*. Nat. Ord. *Personata*, Linn. *Pedicularis*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, turbinate, in five deep, ovate, spreading, slightly unequal, permanent segments. *Cor.* of one petal, bell-shaped, in five deep rounded segments; the three uppermost largest, equal to the calyx; two lower ones shorter, and less coloured. *Stam.* Filaments four, awl-shaped, not half the length of the corolla, scarce visibly unequal, spreading, two at each side, opposite to its lateral fissures; anthers roundish, two-lobed. *Pist.* Germen superior, roundish, compressed; style cylindrical, very short, thicker than the filaments; stigma peltate. *Peric.* Capsule compressed, orbicular, notched, swelling at each side, acute at the margin, of two valves and two cells, the partitions from the centre of each valve. *Seeds* few, roundish-oblong, convex on one side, flat on the other, inserted into a globose central receptacle.

Ess. Ch. Calyx in five deep segments. Corolla five-cleft, irregular. Stamens spreading laterally in pairs. Capsule compressed, inversely heart-shaped, of two cells, with transverse partitions.

1. *S. europæa*. Sibthorpiæ, or Cornish Money-wort.

Linn. Sp. Pl. 880. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 649. (S. prostrata; Salisb. Ic. 11. t. 6. Alfine spuria pusilla repens, foliis Saxifragæ aureæ; Raii Syn. 352. Pluk. Phyt. t. 7. f. 6. Cornwall Penny-wort; Petiv. Herb. Brit. t. 6. f. 11.)—Ray observed this curious little plant to be plentiful in Cornwall and Devonshire, on moist banks, and about the margins of rivulets, flowering from June to August, being accompanied by the elegant *Campanula hederacea*. There several succeeding botanists have gathered both. Loefling found the *Sibthorpiæ* in Portugal, and Mr. Hawkins on the mountains of Crete; but we know not of its having been noticed in any other country. We have seen it completely naturalized on the lawn of James Vere, esq. in his curious garden at Knightsbridge. The root is fibrous, perennial. Stems prostrate, creeping extensively, branched, slender and delicate, leafy, hairy. Leaves alternate, stalked, horizontal, kidney-shaped, with shallow distant notches, hairy, rather fleshy, about half an inch broad; paler and veiny beneath. Flowers axillary, solitary, on short hairy stalks. Corolla of a pale greenish-yellow, with a purplish tinge in the three upper segments.

The *S. involucrea* of Linnæus's *Supplementum* being a very distinct genus, now known by the name of *Dichondra*, see that article, the above becomes the only species of *Sibthorpiæ*.

SIBU, in *Geography*, one of the Philippine islands, about 240 miles in circumference. The principal productions are a species of grain called borona, which serves instead of rice; cotton, tobacco, wax, and civet. This island was discovered by Magellan in 1521. N. lat. 10° 41'. E. long. 123° 30'.

SIBU, Zibu, or *Soglu*, a town in the above-mentioned island, containing 5000 houses, the see of a bishop, and residence of a governor. In this town, as some say, Magellan, the celebrated circumnavigator, died. N. lat. 10° 35'. E. long. 123° 44'.

SIBUCO, a town on the west coast of Mindanao. N. lat. 7° 3'. E. long. 122° 10'.

SIBULTIQUI, a river of Mexico, which runs into the Pacific ocean, N. lat. 13° 35'. W. long. 89° 16'.

SIBUYAN, one of the Philippine islands, about 36 miles in circumference. N. lat. 12° 36'. E. long. 122° 22'.

SIBYLS, SIBYLÆ, supposed by Lactantius, whose opinion is generally followed, to be formed of the two Greek words, *σιβ*, for *Θεο*, *Dei*, and *βουλα*, *counsel*, in *Antiquity*, virgin-propheteesses, or maids supposed to be divinely inspired; and who, in the height of their enthusiasm, gave oracles, and foretold things to come.

Authors do not agree about the number of the Sibyls, though their existence is allowed, as sufficiently established by antiquity. Capella reckons but two, *viz.* Erophyle of Troy, called *Sibylla Phrygia*; and Simuachia of Erythræ, called *Sibylla Erythraea*. Solinus mentions three; *viz.* Cumæa, Delphica, or the Sibyl of Sardis, and Erythræa; and of this opinion is Ausonius, who thus describes them;

“ Et tres fatidicæ nomen commune Sibyllæ,  
Quarum tergemini fatalia carmine libri.”

Ælian makes their number four, *viz.* the Erythræan, the Egyptian, the Sibyl born at Samos, and another of Sardis in Lydia; and Varro increases it to ten, denominating them from the places of their birth; the Persian, called Sabetha by the Persians; Libyan, according to Euripides, the daughter of Jupiter and Latona; Delphic, named Daphne by Diodorus Siculus, who says that she was born at Thebes in Bœotia; Cimmerian; Erythræan, who prophesied to the Greeks, that were going to besiege Troy, the happy success

of their enterprise, and who lived, according to Eusebius, not in the time of the Trojan war, as Varro believes, but under the reign of Romulus; Samian, called, according to Suidas, Pitho, or Persuasion, and according to Eusebius, Eriphile; Cumæan, named Amalthæa by some authors, and by others Demophile or Hierophyle, who is said to have offered to Tarquin the Elder a collection of Sibylline verses, in nine books; Hellepontic or Troiad, born at Marpefus, near the town of Gorgis, in Troas, who lived, according to Heraclides, in the time of Cyrus and Solon; Phrygian, who gave her oracles at Ancyra, the place of her residence; and Tiburtine, named Albunæ, and honoured as a divinity in the vicinity of the river Anio. Of these, the most celebrated are, the Erythræan, Delphic, and Cumæan Sibyls.

Some modern authors, without regarding the authority of Varro, or that of the other ancients, are for uniting all the Sibyls in one; so that, according to them, different names were given to one and the same Sibyl from the different places where she uttered her oracles. She first published her predictions in the city of Erythræa, the place of her nativity; then rambled about the world; and closed her life at Cumæ, in Italy. Dr. Hyde (*De Relig. Perfar.*), shocked at the contradictions and fabulous adventures with which the Pagans filled the history of the Sibyls, accounts for them in the following manner. He observes in the constellation Virgo a bright star, which the Persians called Sambula, denoting, in their language, spica, or an ear of corn; and remarks, that the Persians, who were fond of judiciary astrology, looked on the sign of the Virgin as having a greater power than all the other celestial bodies, for discovering future events. The Greeks, having learnt the sciences of the eastern nations, soon adopted these trifling opinions, and, agreeably to their genius, embellished them with their fictions. Their poets soon invented a Sibyl virgin, in allusion to the term *Sambula*, carried her into several countries, and made her act the part of a prophetess. So that, according to this eminent writer, whatever has been said both by the ancients and moderns of the Sibyls and their prophecies, is entirely fabulous. This conjecture, though ingenious, is contradicted by the testimony of antiquity, which allows that there were, in different times and countries, such extraordinary persons, who were reputed to have a particular fore-knowledge of futurity, and whose predictions, carefully collected, were consulted upon important occasions. The Persian Sibyl might, indeed, owe her original to the circumstance above-mentioned, but that is no sufficient argument against the existence of other Sibyls. The Romans had the highest possible veneration for the Sibyls; and if they did not always regard them as divinities, they at least reputed them of a middle nature between gods and men; and some of them received divine honours. Lactantius says, with confidence, that the Tiburtine Sibyl was worshipped as a goddess at Tibur. Some of them also had temples. Justin Martyr mentions that of the Sibyl of Cumæ, in Italy, built over the cave where she delivered her oracles. Virgil mentions this temple, or rather he considers as a temple the grotto where the Sibyl delivered her oracles, because in after-times there was one actually built there. "Vocat alta in Templâ Sacerdos," *Æn.* l. 6. We may here add, that the inhabitants of Gorgis, in the Lesser Phrygia, had a custom of representing upon their medals the Sibyl who was born in that city, as being their great divinity. As a farther proof of the worship paid to the Sibyls, they had statues erected to them, which were placed in the temples.

The Sibylline oracles were held in great veneration by the more credulous among the ancients; but they were much

suspected by many of the more knowing. The books in which they were written were kept by the Romans with infinite care; and nothing of moment was undertaken without consulting them. Tarquin first committed them to the custody of two patrician priests, instituted for that purpose. (See *DUMVIRI SACRORUM.*) How, when, or by whom this collection was made, are circumstances which authentic history has not ascertained. It is not likely that the Sibyls prophesied in verse, far less that they themselves kept their predictions, and digested them into order. All that we know concerning them is, that a woman came to Tarquin the Elder, as Varro says, or, according to Pliny, to Tarquin the Proud, offering him a collection of these verses in nine books, or three according to Pliny; and that she demanded for them 300 pieces of gold; that when the prince refused to give that sum, she threw three of them into the fire, and asked the same sum for the remaining six, which being refused, she burned three more, and persisted in asking the same sum for those that were left: at length the king, fearing that she would burn the other three, gave her the sum which she demanded. Although this story has very much the air of a romance, it is attested by many authors; and it is certain that the Romans had in their possession a collection of the Sibylline verses.

These books were carefully kept till the civil wars of Sylla and Marius: when the Capitol being accidentally set on fire, and burnt down to the ground, these books were burnt with it. This happened in the year before Christ 83. But the Capitol being again rebuilt about seven years after this period, the senate determined to restore the Sibylline oracles; and having procured many that were said to be of this kind, laid them up in the Capitol, in order to supply the place and office of those that were lost. However, the books thus obtained had been dispersed in the hands of many, and were, therefore, by being thus vulgarly known, unfit for the use which the Romans proposed to make of them. On this account a law was passed, which required the surrender of them, and prohibited any from retaining copies of them, under pain of death. Augustus, when he assumed the high-priesthood of Rome, revived this law, and destroyed a great multitude of copies which were brought in. Tiberius caused many more to be burnt, and preserved only those which were found most worthy of approbation for that service of the state for which they were originally intended; and to these, as long as Rome remained heathen, they had constant recourse; till at length Honorius the emperor, A. D. 399, issued an order for destroying them; in pursuance of which, Stilico burnt all these prophetic writings, and demolished the temple of Apollo, in which they were deposited. Nevertheless, there is still preserved, in eight books of Greek verse, a collection of oracles, pretended to be the Sibylline. Dr. Cave, who is well satisfied that this collection is a forgery, supposes that a large part of it was composed in the time of Adrian, about the year 130; that others were added in the time of the Antonines; and the whole work completed in the reign of Commodus. Dr. Prideaux says, that this collection must have been made between the year of our Lord 138, and the year 167. It could not be earlier, for mention is made of the next successor of Adrian, *i. e.* Antoninus Pius, who did not succeed him till the year 138; and it could not be later, because Justin Martyr, in his writings, often quotes it, and appeals to it; and he did not outlive the year 167. Fabricius supposes that this collection does not contain all the Sibylline oracles which were used by the ancient fathers; and that the most ancient

Christian writers, who have quoted the Sibylline oracles, had only a part of the collection which is transmitted down to us. Some of the fathers, not apprized of the imposition, have often cited the books of the Sibyls in favour of the Christian religion; and hence Celsus takes occasion to call the Christians Sibyllists. It must be allowed that St. Clement, St. Theophilus, and some other Greek fathers of the second century, had a much greater respect for the Sibyls than they deserved; for Dr. Lardner says, that he is well satisfied that the Sibylline verses quoted by them are the forgery of some Christian. The ancient Sibylline verses did not recommend the worship of the one God, condemning all manner of idolatry, as those do which are cited by Justin, Theophilus, and Clement. It must be owned, however, that Clement calls the Sibyl a prophetess, and seems to quote her verses as Scripture, in the strictest sense of the word, together with the Scriptures of the Old Testament; so that if there be any books improperly advanced by him into the rank of sacred Scripture, they are the Sibylline books; but Dr. Lardner does not think that he esteemed them of equal authority with the books of the Jewish canon. It is a circumstance that deserves to be mentioned, that the Heathen people knew nothing of these Sibylline verses till they were found out, or rather forged, by some Christian, and then incantiously and imprudently recommended by others. Justin Martyr seems to have been the first Christian writer who quoted the collection now existing of Sibylline oracles, or any Sibylline verses whatever, containing the peculiar doctrines of Christianity. The more ancient writers preceding him, who have mentioned the Sibyls, have quoted nothing but what might be found in Sibylline writings among the Heathens. In the collection above-mentioned, which appears, for the chief part of it, to have been a work of the second century, we have many unquestionable evidences that the writer, who calls himself a Christian, was acquainted with the New Testament, and that in several places he recites the same facts in the same or similar language. The pretended prophecies of this collection are undeniably taken from the New Testament. Whatever was the particular view of the author in composing this work, says Dr. Lardner, and however improperly some ancient writers have produced testimonies from it in their defences of the Christian religion, it is now of use to us, as it affords an argument that our gospels were extant, and in much repute, in the author's time. See farther on this subject, Prideaux's Conn. vol. iv. p. 885, &c. Lardner's Credib. of the Gospel Hist. vol. iv. book i. cap. 29, or Works, vol. ii.

**SICABA**, in *Geography*, a town on the north-west coast of the island of Negroes. N. lat.  $11^{\circ} 26'$ . E. long.  $123^{\circ} 2'$ .

**SICÆ**, in *Ancient Geography*, a town of Thrace, called in the time of Steph. Byz. Justiniana.—Also, a town of Asia, in Cilicia.—Also, the name of a place in the vicinity of the town of Alexandria.

**SICAL**, or **SISAL**, in *Geography*, a town of Mexico, on the north coast of the province of Yucatan; 60 miles N.W. of Merida.

**SICAMINUM**, in *Ancient Geography*. See **CAIPHA**.

**SICAN**, in *Geography*, a town of Persia, in Khorassan; 15 miles S.W. of Zauzan.

**SICANDERAB**, a town of Hindoostan, in Doab; 36 miles W.N.W. of Pattiany.

**SICANE**, in *Ancient Geography*, a town of Spain. Steph. Byz.—Also, a river of Sicily, which ran near Agrigentum.

**SICANUS**, a town of Spain, according to Thucydides.

**SICAPHA**, a town of Africa Proper, being one of those which were situated between the two Syrtes. Ptol.

**SICARD**, **CLAUDE**, in *Biography*, a Jesuit missionary, was born at Aubergne, near Marseilles, in 1677. He entered into the society of Jesus in the year 1699, and for several years taught the classics and rhetoric in their schools. He was at length sent on a mission to Syria, and thence to Egypt, where he died at Cairo in 1726. He was a man of deep as well as extensive learning, and an exact observer of what was remarkable in the countries he visited. His first publication was "An easy Method of learning Greek," translated into French from the Latin of Peter Gras, with additions. When abroad, he sent home several curious letters, which were published in the "Nouveaux Memoires des Missions de la Compagnie de Jesus dans le Levant;" in which are likewise published his "Plan of a Work on Egypt, ancient and modern," and "A Dissertation on the Passage of the Red Sea, and Journey of the Israelites."

**SICARII**, in *Ancient History*, assassins of Judea, who went about the country for the accomplishment of their nefarious purposes, with short swords concealed under their clothes. Josephus has described them in the most odious colours. Eleazar, he says, the chief man among them, was a descendant of Judas, who had persuaded not a few of the Jews not to enrol themselves, when Cyrenius the censor was sent into Judea. For then the Sicarii conspired against all who were willing to submit to the Romans. They treated all such as public enemies. But other pretences were professed, in order to cover their cruelty and avarice. These hypocritical villains were hired to murder Jonathan, the high priest, at the instigation of Felix. Accordingly, some of the assassins, coming up to Jerusalem, with an apparent purpose of worshipping God; and having short swords under their coats, mixed themselves with the multitude, and killed Jonathan. This murder passing unpunished, the robbers afterwards attended the feasts without any seeming concern, and carrying, as before, swords under their clothes, and mixing with the multitudes, killed several people, some whom they reckoned their enemies, and some whom they were hired by others to destroy. This they did, not only in other parts of the city, but within the bounds of the temple itself. Joseph. De Bell. Jud. l. vii. c. 8. § 1. 5.

**SICASICA**, or **CICACICA**, in *Geography*, a town of South America, and chief place of a jurisdiction of the same name, in the government of Buenos Ayres, 240 miles in extent; 40 miles N.N.W. of Oruro.

**SICAYAP POINT**, a cape on the north-west coast of Mindanao. N. lat.  $8^{\circ}$ . E. long.  $123^{\circ} 30'$ .

**SICCA**, a town on the north coast of the island of Sumatra. N. lat.  $1^{\circ} 32'$ . E. long.  $110^{\circ} 40'$ .

**SICCA**, *La*, a small island in the Mediterranean, near the coast of Naples. N. lat.  $39^{\circ} 58'$ . E. long.  $13^{\circ} 52'$ .

**SICCACOLLUM**, a city of Hindoostan, in the circar of Condapilly, on the Kittuah; 35 miles S.S.W. of Ellore.

**SICCAPILLY**, a town of Hindoostan, in Myfore; 25 miles N.N.W. of Chinna Balabaram.

**SICCA-VENEREA**, **KEFF**, in *Ancient Geography*, a town of Africa, situated about five leagues S.W. of Laribus Colonia, and 25 leagues W.S.W. of Tunis. It was built upon the declivity of a hill. Valerius Maximus says, that it had a temple of Venus, at which young females prostituted themselves, in order to obtain a portion that might enable them to marry.

**SICCHASIA**,

**SICCHASIA**, a word used by some writers to express that uncleanliness at the stomach, and loathing of food, which women are often afflicted with in their pregnancy.

**SICCHOS**, in *Geography*, a town of South America, in the audience of Quito; 20 miles W. of Latacunga.

**SICCINNIS**, in *Antiquity*, a mixed kind of dance.

**SICERA**, in the *Jewish Antiquities*. The Hellenist Jews give this name to any inebriating liquor. St. Chrysostom, Theodoret, and Theophilus of Antioch, who were Syrians, and who therefore ought to know the signification and nature of sicera, assure us, that it properly signifies palm-wine.

Pliny acknowledges, that the wine of the palm-tree was very well known through all the East, and that it was made by taking a bushel of the dates of the palm-tree, and throwing them into three gallons of water; then squeezing out the juice, it would intoxicate like wine.

The wine of the palm-tree is white; when it is drank new, it has the taste of the cocoa, and is sweet as honey; when it is kept longer, it grows strong, and intoxicates. After long keeping, it becomes vinegar.

**SICHAR**, in *Ancient Geography*. See the next article.

**SICHEM**, or **SHECHEM**, called also *Neapolis*, *Sichar* or *Sychar*, and *Maabartha*, a town of Judea, in the tribe of Ephraim, which took up the south side of Samaria. This town was situated on the summit of a mountain, and became one of the strongest and most celebrated towns of this tribe. It was at this place that Abraham lodged, on his way to Canaan (Gen. xii. 6.); and it afterwards became the abode of Jacob, who bought a field in its vicinity, which he gave to his son Joseph, who was buried here. (Gen. xlviii. 22.) Near the same city was Jacob's well or fountain, at which Jesus discoursed with the woman of Samaria. (John, iv. 5.) Joshua gave it to the Levites of the tribe of Ephraim, who belonged to the family of Kohath, the first of the Levites; and it was appointed to be one of the six cities of refuge. (Josh. xxi.) It was at Sichem that Joshua assembled the tribes of Israel (Josh. xxiv. 1.), to renew their engagement of fidelity to God. Sichem was destroyed by Abimelech; but it appears to have been afterwards re-established, because it is said (1 Kings, xii. 2.) that Rehoboam came hither, after the death of Solomon his father; and it was fortified and inhabited by Jeroboam. (1 Kings, xii. 25.) After the ruin of Samaria by Shalmaneser, Sichem was the capital of the Samaritans; and Josephus says (Antiq. lib. xi. cap. 8.), that it was so in the time of Alexander the Great. It was distant, according to Eusebius and Jerom, 10 or 12 miles from Shiloh, 40 from Jerusalem, and 52 from Jericho. Jerom says, that Paula visited the church built on Jacob's fountain; and others, who wrote in the eighth century, speak of this building; but it is not mentioned by Phocas, who wrote in the twelfth century. Sichem or Sichar is now Naplouse, or *Nablous*; which see.

**SICHEM**, or *Sichen*, in *Geography*, a town of France, in the department of the Dyle, on the Demer; 30 miles N.E. of Brussels.

**SICHERFREUTH**, a town of Germany, in the principality of Bayreuth; 3 miles S.E. of Bayreuth.

**SICHLI**. See **SICULI**.

**SICHLAN**, a river of Russia, which runs into the Ochotskoi sea, N. lat. 59° 28'. E. long. 152° 14'.

**SICHOU-LO-HOTUN**, a town of Corea, in the sea of Japan. N. lat. 42° 20'. E. long. 130° 29'.

**SICHIROW**, a town of Bohemia, in the circle of Bolestaw; 3 miles N.N.W. of Purnau.

**SICHTELEN**. See **SUCHTELEN**.

**SICHU**, a town of Mexico, in the province of Mechoacan; 120 miles N.N.E. of Mechoacan.—**Alfo**, a town of Mexico, in the province of Guafleca; 150 miles W.S.W. of Panuco.

**SICIGNANO**, a town of Naples, in Principato Citra; 10 miles W. of Cangiano.

**SICILIAN Measures, Silk, and Vespers**. See the substantives.

**SICILIANA**, in *Botany*, a name given by Dodonæus, and some other authors, to the great androsænum, called *tutsan*, and *park-leaves*.

**SICILIANA**, a pastoral movement in a slow jig-time of 3. The character of this movement requires a point to the first note of almost every triplet. Nothing is more pleasing than the Sicilian strains of great matters. Handel hardly ever fails rendering them characteristic, touching, and pleasing; such as, "He shall feed his Flock like a Shepherd;" "Let me wander not unseen," &c.

**SICILIANE**, or **PASTORALE**, a kind of simple rural music, resounding in Christmas time through all quarters of Naples, and executed by Abruzzese or Calabrian shepherds, upon a species of bag-pipes, called in Abruzzo *zampagne*, and *ciaramelli* in Calabria. The tunes vary, according to the provinces: in the south, they have three different airs; the northern shepherds have only two, to which they add any variations which the boldness of their own genius inspires. The boys learn of their fathers to play upon this instrument, as the means of subsistence. The waits, still kept up in the pay of some corporations in England, are counterparts of these shepherds.

**SICILICUM**, the name of a weight in use among the ancients; which, some say, was equal to three drachms of our weight; others say only to two.

**SICILY**, in *Ancient and Modern Geography*, an island in the Mediterranean, the largest of all the islands in this sea, being about 170 British miles in length, and 70 in medial breadth. Swinburne reckons its greatest length at 210 miles, and breadth 133; and places it between N. lat. 36° 25' and 38° 25', and E. long. 12° 50' and 16° 5'. Sicily is separated from the continent by the Straits of Messina, which, in some parts, are about four miles broad. (See **CHARYBDIS**, **MESSINA**, and **SCYLLA**.) At Messina, and at the mouth of the Straits between the promontories of Pelorus in Sicily and the Lode di Volpa, or Foxes' Tail, in Calabria, is nearly a mile. Many of the ancient historians and poets have stated that this island was formerly joined to the continent, and severed from it, at an unknown period, by some extraordinary convulsion; nor is this opinion at all improbable. Accordingly Pomponius Mela observes, "Sicilia, ut ferunt, aliquando agro Brutio adnexa." To the same purpose Virgil (*Æn.* l. iii. v. 414.) says:

"Hæc loca vi quondam, et vassa convulsa ruina  
Dissiliisse ferunt, cum protinus utraque Tellus  
Una foret. Venit medio vi pontus et undis  
Hesperium siculo latus abscidit."

Silius Italicus details this event more at large (lib. xiv.):

"Ausonia pars magna jacet Trinacria Tellus  
Ut femel expugnante noto, et vastantibus undis  
Accipit freta cærules propulsa tridentis,  
Namque per occultum caeca vi turbinis olim  
Impactum Pelagus lacerata viscera terre  
Dilexit, et medio perumpens arva profundo,  
Cum populis pariter convulsas transtulit urbes."

Claudian asserts positively,

"Trinacria quondam Italiae pars fuit."

Pliny,

## SICILY.

Pliny, Strabo, Diodorus, and many others, both historians and philosophers, are of the same sentiments, and pretend that the strata on the opposite sides of the straits agree perfectly; and some imagine, that this separation is recorded in the name given to Rhegium, a town of Brutium. With regard to the breadth of the strait that separates Sicily from Italy, Silius says, *ubi supra*:

“ Sed spatium, quod dissociat consortia terræ,  
Latratus fama est (sic arcta intervenit unda),  
Et matutinos voluerim transmittere cantus.”

And some persons have even affirmed, that not only the crowing of a cock might be heard from one shore to another, but that a strong voice might be heard through this distance. Mariners have asserted that this canal is not two miles broad.

Sicily, on account of its somewhat triangular form, has been called Trinacria, or Trinacia, and Trinquetra. Its ancient name was Sicania, derived from its inhabitants the Sicani; but when the Siculi took possession of the greatest part of the island, it assumed the name of Sicilia. The interior of Sicily is full of mountains. The ancients, proceeding from the west to the east, enumerated the following; *viz.* Eryx, near the sea and Drepanum, celebrated for a temple of Venus; Cratas, towards the north, in which are the sources of the Eleutherus and Himera, and those of Hypsa, which flowed towards the south; the Gemelli colles, more southerly than the chain of Cratas, in which is the source of the Camicus, and of other rivers; the Nehrodes, northwards and east of the preceding; Maro, still more to the east; the Heræi, from south to north, between the sources of the Himera to the west, and those of Simæthus to the east; and also the famous mount *Ætna*; which see. Among the rivers of Sicily noticed by the ancients, we may enumerate, on the eastern coast, the Simæthus, which rises west of *Ætna*, and south of the town called Engyum, runs towards the south-east, receiving in its course the Chryfas, and discharges itself into the sea near to and north of Murgentium; and the Mela, south of the preceding, and running in a straight direction from west to east; and on the southern coast, the Himera, which had its source in mount Artëfinus, in the environs of Enna, and flowed into the sea at Phicæta; and the Hypsa, which proceeding from the interior of the island, flowed into the sea near to and east of Selinus.

The principal places in ancient Sicily are enumerated and briefly described under their appropriate names in different parts of the Cyclopædia.

Sicily was celebrated among the ancients for its extraordinary fertility. Its mines of lead, copper, and silver, and its variety of stones and volcanic productions, have been recorded by ancient and modern writers; and it has been observed, that the summits of its highest mountains have furnished a great number of different marine productions.

This island has undergone a variety of revolutions: it has been denominated, in very remote times, the island of the Sun, and the land of the Cyclops, and of the Lestrygons. It was afterwards called Sicania and Sicily, from the names of its possessors. The Phœnicians also had establishments in this island, and carried on with it a considerable commerce, in the advantages of which the Trojans are said to have participated. The Greeks established themselves in Sicily for the first time after the siege of Troy, and kept possession of it for a long period, forming different republics, and transporting hither their manners and arts, and different opinions, and erecting temples of stone of the Doric order; and in process of time they shared the government of it with the

Carthaginians. These new conquerors, who about 510 years B. C. gained possession of it, brought with them their commerce, their arms, and their gods. They occupied the western and northern shores, whilst the Siculi retained the midland country; and the southern and eastern coasts were inhabited by the Greeks. The Mamertins arriving hither from Italy took possession of Messina, and called over the Romans, who, urged by their ambition, wanted only a pretext of taking up arms against the Carthaginians. After a variety of successive contests, they took possession of the island. The Romans occupied themselves for some years in establishing peace, abundance, and even splendour; and they erected during the time of the republic superb edifices of marble; their power and ambition setting no limits to their magnificence. Under their dominion Sicily became more flourishing than it had been in the time of the Greeks, when it was considered as free. The Sicilians, under the government of the Romans, lost their military genius, and their mutual jealousies which served only to accelerate their own destruction. When the Romans made themselves masters of Sicily, they permitted the inhabitants to retain the temples, the deities, and the forms of worship which the Greeks and other nations had established among them, and till the division of the Roman empire, they maintained a certain character of elegance and refinement. But at this period the monuments of antiquity sunk into neglect; the arts were no longer held in estimation; and talents disappeared on the access of ignorance and barbarism. Towards the end of the fourth century, Syracuse was the first town of Sicily that received Christianity, and soon after other towns and the whole country followed its example; and this event was followed by a neglect of their temples and public monuments. The ignorance of the priests, no less notorious than the fervour of their zeal, induced them to make war against the sciences and the arts, that they might thus the more effectually and speedily destroy Paganism, which cultivated them.

The Sicilians, having relinquished all martial ideas during a long series of generations, turned their attention solely to the arts of peace, and the labours of agriculture. Their position in the centre of the empire preserved them from both civil and foreign foes, except in two instances of a fertile war. But the rapacity of their governors was a more constant and insupportable evil. In this state of apathy and opulence, Sicily remained till the seventh century of our era, when the Saracens began to disturb its tranquillity. The barbarous nations of the North had previously invaded and ravaged its coasts, but had not long kept possession. The Saracens, however, were more fortunate. In the year 827 they availed themselves of quarrels among the Sicilians to subdue the country; and they chose Palermo for their capital. The standard of Mahomet triumphed about 200 years. In 1038 George Maniæres was sent by the Greek emperor with a great army to attack Sicily. He made good his landing, and pushed his conquests with vigour, and, aided by the valour of some Norman troops, with success. Maniæres recompensed them with ingratitude; and by his conduct allowed the Mussulmen an interval of tranquillity, and the Normans an opportunity and pretext of invading the imperial dominions in Italy. Robert and Roger of Hauteville afterwards conquered Sicily on their own account. After a struggle of ten years, the Saracens, in 1072, as Swinburne says, surrendered the rich prize; though others say, that they lost the possession of it A.D. 1058. Robert ceded it to his brother Roger, who assumed the title of *great earl* of Sicily. This first sovereign swayed the sceptre with wisdom and glory, and deservedly ranks among the greatest characters

## SICILY.

ters in history. He was succeeded by his son Simon, who, after a short reign, made way for a second son called Roger, the first king; who, in 1127, joined to his Sicilian dominions the whole inheritance of Robert Guiscard, and assumed the regal title. Roger, it is said, was named king of Sicily by the pope, A.D. 1130. During his reign, Sicily enjoyed profound peace. The reign of his son William I. who ascended the throne in 1154, was a period of war and confusion. During the reign of Frederick I. a German, the Saracens, who had revolted, were removed to Puglia, 400 years after the conquest of Sicily, by their ancestors. The Norman line continued till their kingdom was subdued by Henry VI. emperor of Germany. After the battle of Benevento, Sicily submitted to Charles of Anjou, a prince of the French line, A.D. 1266, and having endured quietly for a considerable time oppression and wanton cruelty, at length determined to emancipate itself from his tyranny. Accordingly an insurrection took place in 1282, and after the Sicilian vespers, the insurgents offered their crown to Peter I. king of Aragon, who accepted and defended it against all the efforts of his antagonist, and the thunders of the Vatican. On the death of Alphonso the Magnificent, who succeeded his father Ferdinand I. of Castile, Naples was added to his other dominions; and after his decease in 1458, the history of Sicily becomes uninteresting. At the peace of Utrecht, Sicily was ceded to Victor, duke of Savoy, who soon after was compelled by the emperor Charles VI. to relinquish it, and accept Sardinia as an equivalent.

For further particulars relating to the history of Sicily, we refer to NAPLES.

The climate of Sicily is very hot; the thermometer at Palermo varying in June and July from  $73\frac{1}{2}^{\circ}$  to  $80\frac{1}{2}^{\circ}$ , and when the sirocco wind blows, rising suddenly to 112. March is the only month in which any chilling winds are felt, and even in the beginning of January the shade is refreshing. The appearance of winter is only seen in the snow that falls on the summit of mount *Ætna*. (See that article.) Although the island has, in many parts of it, the aspect of a rock, the soil is singularly fertile, but it is not now cultivated as it was formerly, when it was reckoned the granary of Rome. The crops of wheat are still so abundant, notwithstanding the oppression of the government, as not only to supply the wants of its own inhabitants, but to afford a large surplus for exportation; and if this island enjoyed the blessing of a free government, it might become one of the richest and most flourishing in the world; for even in its present wretched state of cultivation, one good crop, says Brydone, would be sufficient to maintain the island for seven years; but when he visited the island, the exportation of this commodity had been prohibited for several years past, or, at least, to all such as were not able to pay most exorbitantly for that privilege. The sugar-cane was formerly very much cultivated in this island, but the duties imposed were so enormous, that it has been almost totally abandoned. Silk afforded formerly a profitable branch of trade, but this has very much declined. Besides wheat, which has at all times constituted the riches of this island, they cultivate many other branches of commerce, though none that could bear any proportion to this, were it under a free government, and exportation allowed. Their granaries are so contrived, by excluding the air and keeping the grain dry, as to preserve it for many years. Large quantities of barley and pulse grow in Sicily, but very little oats or millet. Canary-bird seed is exported to a large amount, and is almost peculiar to this island. Large quantities of oil are exported from places on the north side of the island. Wine and brandy are exported in great abundance; and the wines are very va-

rious. The fisheries, also, are very productive, and great quantities of tunny, anchovies, and sardines, are salted, and sent from the vicinity of the places where they are caught. The art of manufacturing silk, and of the management of the insects that produce it, was established here by Roger, king of Sicily, and it was communicated from hence to the western countries of Europe.

Silk is considered as the second great source of riches to Sicily, corn being undoubtedly the first; a quantity of silk, equal in value to a million of ducats (187,500*l.*) is annually exported. Palermo and Messina alone send it out; a considerable quantity of the materials is manufactured in both places; but Palermo, which employs nine hundred looms, exports very little, most of its silks being used at home. Messina employs twelve hundred looms, and Catania rather more. In the Messinese manufactures a variety of silks is made, but the silk is seldom well drawn, dyed, or matched, and the work is apt to prove hard and to rub. Most of it goes to the Levant.

A large quantity of barilla is shipped from the southern coast. The whitest and heaviest salt is produced at Trapani. This island also furnishes fumach, hare and rabbit-skins, rags, sulphur, &c. for exportation.

Soda is a commodity of which they have an ample supply, and they every year send great quantities of it to the glass-houses at Venice. They have likewise a considerable trade in liquorice, rice, figs, raisins, and currants, the best of which grow among the extinguished volcanoes of the Lipari islands. Their honey, which is gathered three months in the year, viz. July, August, and October, is very highly flavoured, and in some parts of the island superior to that of Minorca. Although sugar is now no article of Sicilian commerce, enough is made for home consumption; and the sugar-cane is said to thrive very much in several parts of the island. It is said, that towards the north of Sicily they find the shell-fish that yields a kind of flax, of which gloves and stockings are made. Their plantations of oranges, of which 2000 chests are shipped annually from Messina, lemons, bergamots, almonds, &c. afford no inconsiderable branch of commerce. The pistachio-nut is likewise much cultivated; their manna and alum are likewise very profitable. The cantharides fly, which is found on several trees of *Ætna*, is also a Sicilian commodity. These cantharides are said to be preferable to those of Spain. Sicily abounds with mineral springs of both hot and cold water; some of which throw up an oil that is applicable to various purposes. The marbles of Sicily would afford a great source of opulence, if there were any encouragement to work the quarries; and they have also other stones that are serviceable in a variety of ways.

It would, however, be endless to give an account of all the various commodities and curious productions of this island; *Ætna* alone affords a greater number than many of the most extensive kingdoms, and is no less an epitome of the whole earth in its soil and climate, than in the variety of its productions. Besides the corn, the wine, the oil, the silk, the spice, and delicious fruits of its lower region;—the beautiful forests, the flocks, the game, the tar, the cork, the honey, of its second;—the snow and ice of its third; it affords from its caverns a variety of mineral and other productions; cinabar, mercury, sulphur, alum, nitre, and vitriol; so that this wonderful mountain at the same time produces every necessary, and every luxury of life.

Its first region covers their tables with all the delicacies that the earth produces; its second supplies them with game, cheese, butter, honey; and not only furnishes wood of every

# SICILY.

kind for building their ships and houses, but likewise an inexhaustible store of the most excellent fuel; and as the third region, with its ice and snow, keeps them fresh and cool during the heat of summer, so this contributes equally to keep them warm and comfortable during the cold of winter.

The principal trade of this island is carried on at Palermo and Messina; the former consumes of imports four or five times more than the latter; but on account of lighter duties, Messina exports a greater quantity of silk, and supplies the inland towns with more commodities. The business of other places on the coast consists solely in shipping corn, wine, salt, &c. Trapani, on account of its famous salt-pans and the shipping belonging to it, is one of the busiest commercial towns in the island.

According to the enumerations made in 1714, says Swinburne, Sicily contained 1,133,163 inhabitants, including 40,000 ecclesiastics, and 110,000 inhabitants of Palermo. In 1615 it contained 1,107,234; in 1505, 488,500, without reckoning the inhabitants of Palermo or Messina.

When Mr. Brydone visited the island in the year 1770, he says that the inhabitants, by the last enumeration, amounted to 1,123,163, of which number there were about 50,000 that belonged to the different monasteries and religious orders: the inhabitants of Palermo were computed at 150,000. The number of houses in the island were estimated at 268,120; so that allowing the enumeration and the estimate to be just, the number to a house appears to have been between five and six. The vicissitudes and commotions that have more recently occurred have not been favourable to an increase, but must rather have contributed to a diminution of the population.

The provinces in this island are three: viz. Val di Noto, 260 miles in circumference; Val di Mazara, 302 miles in circumference; and Val Demona, 313 miles in circumference: they contain 42 towns belonging to the demesne, and 310 baronial.

Sicily is governed by a viceroy, in whose absence the archbishop of Palermo is regent. The general assembly of parliament is composed of 66 archbishops, bishops, abbots and priors, which form the braccio ecclesiastico: 58 princes, 27 dukes, 37 marquises, 27 counts, 1 viscount, and 79 barons, form the militaire; and the demaniale consists of 43 representatives of free towns. Out of each braccio four deputies are chosen to conduct public business; but the viceroy, the prince of Butera, and the prætor of Palermo, are always the three first. N.B. There are many titled persons that have no seat in the assembly, viz. 62 princes, 55 dukes, 87 marquises, 1 count, and 282 other feudatories.

The ecclesiastical government consists of three archbishoprics and seven bishoprics.

The following tables shew the coins, weights, and measures of Sicily.

## TABLES OF SICILIAN COINS.

Gold Coins.	Silver Coins.
1. Piece of 6 ducats, or double ounce.	Scudo, equal to 12 taris.
2. Piece of three do. or onza.	Ducat - - 10
3. Piece of two ditto.	Mezzo scudo - 6
4. Piece of one ducat and a half.	Terzo di scudo - 4
	Piece of three tari 3
	— of two tari, equal to the tari of Naples.
	The tari, equal the carlino of Naples.

## Brass Coins.

Grano, equal to six Neapolitan calli, or half a grano.  
Mezzo-grano, equal to three calli of Naples.  
Other subdivisions are seldom met with.

The ounce, or onza	} is equal to {	3 ducats, or 30 taris.
The scudo		12 taris.
The ducat		10 taris.
The tari		20 grano.
The grana		6 piccioli.

Accounts are kept in onza, tari, and grano. Upon an average, the ducat is worth forty-five pence English money.

## WEIGHTS AND MEASURES.

There are two sorts of weights used in Sicily.

### 1. Grande.

1 Cantaro contains 110 rotoli	} This cantaro is equal to 215 pounds avoirdupois weight.
1 Rotolo - 33 ounces	
1 Pound - 12 ounces	
1 Ounce - 30 trapeli	

### 2. Common.

1 Cantaro contains 100 rotoli	} This cantaro is equal to 178 pounds weight avoirdupois.
1 Rotolo - 30 ounces	

## DRY MEASURE.—Corn.

- 1 Salma generale contains 16 tomoli—equal to 20 Winchester bushels, used in measuring wheat.
- 2 Salma a la grossa contains 20 tomoli—equal to 24 Winchester bushels, used for barley, beans, &c.

## LIQUID MEASURE.—Oil.

1 Cassis weighs 18 pounds avoirdupois.

Wine.—1 Salma contains 8 quartari. 1 Quart contains 12 quartucci.

## LINEAL MEASURE.

- 12 Oncie make 1 palmo, equal to 10 inches 3 lines.
- 8 Palmi make 1 canna, equal to 6 feet 8 inches.

Besides the obligations which the Romans had to the Etruscans and Greeks for their taste and knowledge in the fine arts, the conquest of Sicily 200 years before the Christian era, contributed greatly to their acquaintance with them. Indeed, there was no state of Greece which produced men of more eminence in all the arts and sciences than Sicily, which was a part of Magna Græcia, and which having been peopled 719 years B.C. by a colony of Greeks from Corinth, their descendants long after cherished and cultivated science of all kinds, in which they greatly distinguished themselves, even under all the tyranny of government with which they were oppressed. Fabricius gives a list of seventy Sicilians who have been celebrated in antiquity for learning and genius, among whom we find the well-known names of Æschylus, Diodorus Siculus, Empedocles, Gorgias, Enclid, Archimedes, Epicharmus, and Theocritus. To the Sicilians is given not only the invention of pastoral poetry, but of the wind instruments with which the shepherds and cowherds used to accompany their rural songs.

After the conquest of Greece, the Romans had the taste to admire and adopt the Grecian arts. And the president Montefiquieu remarks, with respect to the military art, that one of the chief causes of the Roman grandeur, was their method

method of abandoning their ancient customs, and adopting those of the people whom they had vanquished, whenever they found them superior to their own.

**SICIMA**, in *Ancient Geography*, a town of Palestine, in Samaria, according to Josephus.

**SICINOS**, or **PHOLEGANDROS**, the name of one of the Cyclades islands; situated S.E. of Siphnos, E. of Melos, and W. of Jos, and very near it.

**SICION**, in *Geography*, a small island in the Indian sea, near the coast of Africa. S. lat.  $12^{\circ} 35'$ .

**SICK HERRINGS**. See **HERRING**.

**SICK**, *Iron*. See **IRON SICK**.

**SICKHERY**, in *Geography*, a town of Hindoostan, in the circar of Gohud; 5 miles N. of Lahaar.—Also, a town of Hindoostan, in the circar of Gohud; 10 miles S.E. of Kooch.

**SICKLE**, in *Agriculture*, a toothed hook, with which corn is reaped.

There is considerable variety in the construction of the tools which are employed for this purpose in different places; and which, in some, are denominated *sickles*, but in others *hooks*. Some of them are also used in one part of the country, and some in another, being wholly unknown in others.

The *common sickle* is a sort of femicircular piece of wrought iron faced with steel, which in general is from about twenty to thirty inches in length, and about half an inch in breadth, having a sharp toothed-edge cut in the steeled part, from twenty-six to thirty teeth being formed in every inch in length. The teeth all incline towards the handle of the tool, so that it only cuts when it is drawn towards the person using it, and not when introduced through the standing corn in the act of reaping. The Furness sickle, a valuable tool of this kind, made use of in a district of that name in the northern part of Lancashire, has a blade two feet six inches long, edged with fifteen teeth in every inch, and in the span of its curvature, measures two feet from the heel to the point. It is a powerful tool, and capable of doing much work in a given time when in good hands, as seen below.

The *smooth-edged sickle*, or reap-hook, has a shape and length which are much the same as those in the common sickle, only a little broader; but the edge is smooth or sharp and without teeth.

The *badging* or *bagging sickle* or hook is a tool of the same kind, but which is a great deal larger and heavier, as well as broader at the point. It can, however, be used with great effect and expedition by those who are accustomed to this mode of reaping.

The *sickle-hook* is also another tool of this nature, which is made use of in some districts. It is only toothed from about the middle to the point end, by which the waste of grain in cutting is said to be prevented.

By much the most ancient of these tools is the common sickle, and it is probably, on the whole, the best of them, though it is getting much out of use in many parts of the country, being now even scarcely known or employed in the counties of Devon, Cornwall, and Somerset, and many other places in the more western districts of the kingdom, having long since given place to the hooks, the reason of which seems to be the greater ease of performing the work by them, as is commonly supposed, but by no means proved. The sickle is by far the most frugal and economical tool for accomplishing the work with, as causing the least loss of grain. Trials made with the sickle and the reap-hook, have indeed shewn that the latter tool is more expeditious, but at the same time that the loss of grain is far

greater, being estimated at not less than five-sixths of the whole in scattered corn.

This difference is supposed to be produced by the hook having a sharp smooth edge, which cuts the stems, as it is put into the standing corn, before it is gathered into the left hand of the workman; while the sickle having a fine-toothed edge inclining towards the heel part, as has been already seen, does not cut the straws as it is put into the standing crop. Thus, though the hook will execute the work with greater facility, where the workman must have ease, the best mode will probably be to have recourse to the sickle-hook, by means of which, from the manner of its being edged, it will much prevent the above enormous loss of corn which is caused in other ways of doing the business.

It is necessary for the farmer to be aware of this difference in the use of the different tools of the sickle kind, as the hooks are fast introducing themselves into the eastern and even the northern parts of the kingdom, as well as into Ireland, where they were formerly unknown, and prevail much in many other places.

In the above district of Furness, the reaping is wholly and most excellently performed by means of the sickle. At an easy rate of working, three men, it is said, with this tool, will cut a customary acre of six yards and a half to the pole or perch, of long, light, slender corn, bind and flouk the same in the course of a day, or less than fourteen hours; and five men with these tools will perform the same quantity of work in a field of the strongest corn, when laid and much entangled. By hard labour from light to dark, three men with this sort of tool will reap, bind, and flouk above a customary acre of any kind of grain. See **HARVESTING** and **REAPING of Corn**.

**SICKLE-Fish**. See **FALX**.

**SICKLE-Word**, in *Botany*. See **CORONILLA**.

**SICKLUPEN**, in *Geography*, a town of Prussia, in the province of Samland; 5 miles N. of Tiltit.

**SICKNESS**. See **DISEASE**.

**SICKNESS**, *Falling*. See **EPILEPSY**.

**SICKNESS**, *Green*. See **CHLOROSIS**.

**SICKNESS**, *Sweating*. See **SWEATING Sickness**.

**SICKRÉE**, in *Geography*, a town of Bengal; 26 miles W.N.W. of Ramgur.

**SICLOS**, a town of Hungary, having a castle on a mountain, in which the emperor Sigismund was imprisoned; 64 miles S.E. of Canischa.

**SICLYGULLY**, a town of Bengal; 15 miles N. of Rajamal.

**SICON**, a town of the island of Cuba; 125 miles W.S.W. of Havana.

**SICUB**, or **SICUP**, in *Natural History*, a name given by the inhabitants of the Philippine islands to a species of hawk, of the bigness of their common hawk, or banoy, which is somewhat larger than our sparrow-hawk. This bird is very elegantly variegated all over its body with yellow, white, and black. See **LAVIN**.

**SICULI**, in *Ancient Geography*, a people originally of Dalmatia, who established themselves in Italy about the 16th century B. C. They formed a numerous nation, and had possession of a considerable extent of country; as they peopled Umbria, Sabina, Latium, and all the canton, the occupiers of which were afterwards known under the name of Opici. The Siculi passed into Sicily, and gave it their name. This event is said to have taken place, according to Hellanicus of Lesbos, 80 years before the siege of Troy, or 1364 years B. C. according to the chronology of Timocydides. The name of Siculi, which comprehended all the people who diffused themselves from the Tiber to the eastern

extremity of Italy, the country occupied by the Liburni excepted, was gradually abolished by the separate leagues and distinctions of the Sabines, Latins, Samnites, Oenotrians, and Italians. Herodotus, Thucydides, Plato, and Aristotle, mention these people.

**SICULIANA**, in *Geography*, a town on the S. coast of Sicily, containing 5000 persons, and belonging to the prince of La Catholica, to whom it yields an annual income of 14,000 crowns. It is remarkable for not having a single convent within its precincts, owing either to the danger of a visit from the Mahometans, or to the recent foundation of the town. The ignorance of the inhabitants, at least with regard to philology, is remarkably evinced by an anecdote mentioned by Swinburne. On the wall of his apartment he found notice of a thesis to be maintained in the schools of Girgenti by a native of Siculiana: in which he undertakes to prove, "that the Copernican system is impious, absurd, and contradictory to Holy Writ, from which it is evident, that the earth stands still, and the sun moves round it, like the sails of a windmill round the pivot." Siculiana is pleasantly situated on two hills joined together by a long street; the vale below being full of orange and other fruit-trees, and the view of the sea very extensive; 12 miles N.W. of Girgenti.

**SICULONES**, in *Ancient Geography*, a people who inhabited the Cimbric peninsula, according to Ptolemy.

**SICULOTÆ**, a people of Dalmatia, who, according to Ptolemy, were divided into 24 decuriæ.

**SICUM**, a town of Illyria, on the coast of Dalmatia, between Scardona and Salone, according to Ptolemy and Pliny. The latter says, that the emperor Claudius sent hither his veteran soldiers.

**SICUS**, in *Ichthyology*, a name used by some authors to express that species of coregonus, called by the generality of authors *Abula nobilis*. This, in the Linnæan system, is a species of *Salmo*.

**SICUT ALIAS**, in *Law*, a writ sent out in the second place, where the first was not executed.

It is thus called from its beginning, which is in this form: "Georgius, D. G. &c. Vicecomiti Heref. salutem. Præcipimus salutem tibi (sicut alias) præcipem," &c.

**SICYANA**. See *Gourd WORM*.

**SICYEDON**, from *σικωσις*, a cucumber, in *Surgery*, a transverse fracture.

**SICYON**, in *Ancient Geography*, a town of Greece, and capital of a small state in the gulf of Corinth, and not far distant from it. It was anciently called Ægiæ, from Ægiæus, its supposed founder and first monarch. It is not certain whether the whole kingdom, or only its metropolis, was called by that name, but it was exchanged for Apia, from Apis its fourth king; and in process of time it acquired that of Sicyon, who was the 19th monarch. He reigned about 740 years after its supposed foundation; and from that time not only the kingdom, but the whole peninsula of Peloponnesus, was called Sicyonia until its dissolution.

This little kingdom lay on the N. part of the Peloponnesus, since called the bay of Corinth. On the west it had the province of Achaia, and on the east the isthmus, which joins the peninsula to the continent of Greece. Its extent has not been ascertained. Its capital is supposed to have been situated upon the river Alopus, having the bay of Corinth on the north, and the rest of the Peloponnesus at the three other points. Strabo and Livy say, that it was parted from the kingdom of Corinth by the river Nemia; and Ptolemy adds that it was first called Micone, and afterwards Ægiæ; he gave it two cities, Platius and Sicyon, both of which he placed at some distance from the sea.

The territory of this small state was rich, abounding with corn, vines, olive-trees, and other commodities, besides some iron mines. Its metropolis was, in process of time, very much adorned by Sicyon and his successors, with temples, altars, monuments, and statues of all their gods and ancient monarchs. This would be justly deemed the most ancient monarchy in the world, not excepting those of Egypt and Assyria, if it were true that its founder lived about 150 years after the flood, or about 200 years before Noah's death; as some have computed it from Eusebius, who affirms this monarchy to have been founded 1313 years before the first Olympiad, or 2089 B. C. But other chronologers have corrected this mistake, and made him contemporary with Terah, Abraham's father, and stated the commencement of his reign about the year of the world 1915, or even later, about A. M. 1236; by which computation it is brought somewhat lower than the year of the flood 900. This kingdom is said to have had, during an interval of 962 years, a succession of 26 kings, but their reigns are distinguished by no memorable action or conquest. The first king was Ægiæus, and the last Zeuxippus or Deuxippus; but in Blair's chronology the last king is Charidemus, with whom they end, 1089 years B. C. or 15 years after the return of the Heraclidæ into Peloponnesus. In the list of kings, the most remarkable is Sicyon, who gave name to the state, and who is supposed to have built, or at least enlarged, the metropolis of the kingdom, and to have called it by his own name. Accordingly it was not only one of the noblest cities in Greece, on account both of its magnificent edifices and ingenious workmen, but it was a considerable place when the Venetians were masters of the Morea, under the new name of "Basilica," though it has been for near the two last centuries reduced to a heap of ruins, containing only three Turkish, and about as many Christian families. The town was situated on the top of a hill, about three miles from the gulf of Lepanto; and has still several monuments of its ancient as well as modern grandeur, particularly the walls of its famous citadel, of some fine churches and mosques, and a large ancient edifice, called the royal palace, with aqueducts to supply it with water, all which, with other old remains, are described by sir George Wheeler, Voy.

After the death of Zeuxippus, the last king of Sicyon, this state is said to have been governed by the priests of Apollo Carneus, five of whom held the sovereignty only during one year each; after which the Amphictyons (swayed the sceptre nine years successively, and Charidemus, the last of them, continued in it 18 years. After this hierarchy had lasted 32 years, the Heraclidæ, who were at that time returned from Peloponnesus, became masters of it, or according to Pausanias, the kingdom was incorporated with the Doræ, and became subject to that of Argos, the next kingdom to that of Sicyon in respect of antiquity. Anc. Un. Hist. vol. v.

**SICYONE**, a word used by Hippocrates to express colocyath, and by others for a species of hard-shelled gourd, in the shape of a pear, and by some for a cupping-glass.

**SICYONEUM OLEUM**, a word used by the ancients to express a medicinal oil, of which there were among them three kinds in use. The first was called *sicyonium simplex*. This was composed of two ounces of the root of the wild cucumber, boiled several hours in a pint of oil. The second sort was called the *compound sicyonium*, and was made of the root of the same plant, with many other ingredients. The third was another compound kind, made not with an infusion of the root, but with the juice of the fruit of the wild cucumber.

**SICYONII**, among the Romans, were shoes of a more delicate

delicate form, and better ornamented than ordinary, and chiefly worn by the ladies and the gallants.

**SICYOS**, in *Botany*, a name borrowed from the ancient Greeks, whose *σικυος* is supposed to be our common cucumber, or very near it. The genus before us belongs to the same tribe.—Linn. Gen. 509. Schreb. 664. Willd. Sp. Pl. v. 4. 625. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 349. Pursh v. 2. 444. Juss. 394. Lamarek Illustr. t. 796. Gært. t. 88. (Sicyoides; Tourn. t. 28.)—Class and order, *Monoclea Polyadelphia*. (Linnaeus and his followers refer it to *Monoclea Syngenesia*, and Willdenow to *M. Monadelphia*; see MOMORDICA.) Nat. Ord. *Cucurbitaceae*, Linn. Juss.

Gen. Ch. Male, *Cal.* Perianth of one leaf, bell-shaped, with five small awl-shaped teeth. *Cor.* bell-shaped, in five deep ovate segments, united to the calyx. *Stam.* Filaments three, awl-shaped, short, connected at the base; anthers two on each of two filaments, one on the third, (*Juss.*)

Female on the same plant. *Cal.* Perianth as in the male, superior, deciduous. *Cor.* as in the male. *Pist.* Germen inferior, ovate; style cylindrical; stigma tumid, three-cleft. *Peric.* Berry ovate, beset with spines, of one cell. *Seed* solitary, nearly ovate.

Eff. Ch. Male, Calyx with five teeth. Corolla in five deep segments. Filaments three.

Female, Calyx superior, with five teeth. Corolla in five deep segments. Style three-cleft. Berry with one seed.

1. *S. angulata*. Angular Single-seeded Cucumber; or Chocho Vine. Linn. Sp. Pl. 1439. Willd. n. 1. Ait. n. 1. Pursh n. 1. (Bryonioides flore et fructu minore; Dill. Elth. 58. t. 51. f. 59. Cucumis bryonioides bisnagarica, fructu parvo, florum calyce mucricato; Pluk. Phyt. t. 26. f. 4. C. canadensis monospermos, fructu echinato; Herm. Parad. t. 133; ibid. p. 108, Bryonioides canadensis, &c.)—Leaves five-angled, minutely toothed, rough; heart-shaped, with an obtuse sinus, at the base.—On the banks of rivers, from Canada to Carolina, flowering in June and July. *Pursh.* The root is annual. *Stem* branched, hairy, weak, climbing by means of long, spiral, divided tendrils. *Leaves* alternate, on long stalks, pointed, more or less toothed, minutely rough, three or four inches broad. *Flowers* whitish, marked with green lines, axillary; the male ones racemose, on a long stalk; female on a much shorter stalk, and capitate. *Fruit* ovate, pale, spinous, half an inch long, about eight or ten together in a round head. *Seed* large, ovate, smooth.

2. *S. parviflora*. Small-flowered Single-seeded Cucumber. Willd. n. 2.—“Leaves five-angled, minutely toothed, smooth; heart-shaped, with a roundish sinus, at the base.”—Native of Mexico. Communicated to professor Willdenow, by the celebrated baron Humboldt, from whose seeds it was raised at Berlin. Annual, like the last, and much resembling it, but the leaves are not rough, nor is their sinus an obtuse angle, but round. The male flowers are not one-tenth so large as in *S. angulata*; the female ones about a quarter the size of that species. The fruit however is but little smaller. *Willdenow.*

3. *S. vitifolia*. Vine-leaved Single-seeded Cucumber. Willd. n. 3.—“Leaves five-lobed, toothed, hairy and viscid; heart-shaped, with a roundish sinus, at the base.”—Willdenow saw this species in a living state, but was unacquainted with its native country. He describes it as annual, differing widely from both the preceding in having the leaves divided half way down into five lobes, clothed, like the whole plant, with fine viscid hairs, and smelling like *Salvia coccinea*. Male as well as female flowers half the size of the first species.

4. *S. laciniata*. Jagged-leaved Single-seeded Cucumber. Linn. Sp. Pl. 1439. Willd. n. 4. (Sicyoides fructu echi-

nato, foliis laciniatis; Plum. Ic. 239. t. 243. f. 1.)—Leaves deeply five-lobed, laciniated.—Native of South America.—By Plumier's figure, this species seems to differ from all the foregoing in its deeply divided and jagged leaves, which are very rough on the upper side. The fruit appears more rounded and obtuse than in *S. angulata*.

*S. Garcini*, Linn. Mart. 297. Burm. Ind. t. 57. f. 3. is rightly, we believe, referred to *Bryonia* by Willdenow, in his Sp. Pl. v. 4. 623. Burmann mistook the stipula for the fruit, a rare instance of the kind!

**SID**, in *Geography*, a small river of England, which runs into the English Channel, at Sidmouth.

**SIDA**, in *Botany*, a name borrowed from the Greek, whose *σιδα* has by some been thought a kind of marsh mallow, nor can we find any other reason for the present application of this name. Theophrastus describes his *σιδα* more particularly than usual, and evidently indicates a species of *Nymphaea*. Lexicographers call *σιδα* the Pomegranate, and Dioscorides uses the word *σιδα* for the rind of that fruit.—Linn. Gen. 352. Schreb. 463. Willd. Sp. Pl. v. 3. 734. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 197. Pursh v. 2. 452. Cavan. Diff. 6. Juss. 273. Lamarek Illustr. t. 578. Gært. t. 134. (Abutilon; Tourn. t. 25. Anoda; Cavan. Diff. 38. Juss. 273.)—Class and order, *Monadelphia Polyandria*. Nat. Ord. *Columniferae*, Linn. *Malvaceae*, Juss.

Gen. Ch. *Cal.* Perianth inferior, simple, of one leaf, angular, cut about half way down into five segments, permanent. *Cor.* Petals five, dilated upwards, emarginate, attached by their claws to the tube of the stamens. *Stam.* Filaments numerous, united below into a tube, separating at the upper part of the tube into capillary segments; anthers roundish. *Pist.* Germen orbicular; styles five, ten, or more, more or less combined below; stigmas capitate. *Peric.* Capsule roundish, angular, depressed, of as many cells as there are stigmas, more or less combined at the base, each with two pointed valves, bursting at the upper part. *Seeds* one or more in each cell, roundish, generally pointed; convex at the outer side; angular at the inner, by which they are attached to the central column.

Obf. This genus includes the *Melvinia* of Dillenius, which has five cells only, with solitary seeds, as well as his and Tournefort's *Abutilon*, whole cells, as well as seeds for the most part, are more numerous. *Anoda* of Cavanilles is very insufficiently distinguished, by the cells of the capsule being rather more united than usual; but there is no clear or decided difference. For the distinctions of *NAPAEA*, referred to *Sida* by Cavanilles, Schreber, &c. see that article. The fruit of the Linnean *S. periploisifolia* seems peculiar, having two series of cells, according to Schreber.

Eff. Ch. Calyx simple, angular. Style in numerous divisions. Capsule of several bivalve cell, spreading from a centre.

An extensive genus, including most of the columniferous or malvaceous order, that have no external calyx. Cavanilles and L'Heritier have considerably added to the quantity of species. Their number in the 14th edition of Linn. Syst. Veg. is only 27; from which the list of all, being Schreber's *PALAVIA*, is to be expunged. (See that article.) Willdenow reckons up 99, but from these are to be deducted the two *Napaea* of Linnaeus, which undoubtedly constitute a distinct genus, as we have shown in its proper place. In their stead, however, there are two added from North America. Most of the species are tropical plants, natives of the East or West Indies. Several are found in Mexico and Peru; eight in North America; a few at the Cape of Good Hope, the Mauritius, &c.; and nearly wild

in Europe, though *S. Abutilon* is reported to grow in Siberia and Switzerland, where it may perhaps have been naturalized; as has happened to various tropical annuals in colder climates than what is natural to them. Abyssinia has afforded one new species to our gardens; besides which, 34, exclusive of the *Napeæ*, are enumerated in Mr. Aiton's valuable work.

The habit of all is more or less shrubby, though several have annual roots. The leaves are alternate, stalked, simple; either entire, notched, or lobed. Inflorescence mostly axillary. Flowers yellow, reddish, or white. The species are disposed in sections, according to the shape of the foliage. We shall give various examples.

SECT. 1. *Leaves lanceolate, more or less narrow, oblong, or ovate.* Seventeen species.

*S. angustifolia.* Narrow-leaved Sida. Murray in Linn. Syst. Veg. ed. 14. 621. Willd. n. 2. Ait. n. 1. L'Herit. Stirp. 89. t. 52. Cavan. Diff. 14 and 48. t. 2. f. 2.—Leaves linear-lanceolate, toothed. Stipulas setaceous, with axillary spines. Flower-stalks simple, mostly solitary. Capsules with beaked valves.—Native of Brasil. Perennial, with a shrubby, branched, downy stem, three feet or more in height. Leaves pale and downy beneath, about two or three inches long, half an inch broad, on short stalks, accompanied at the base by two or three minute spines, as well as erect narrow stipulas. Corolla pale, yellow, oblique.

*S. spinosa.* Prickly Sida. Linn. Sp. Pl. 960. Willd. n. 6. Ait. n. 2. Pursh n. 1. Cavan. Diff. 11. t. 1. f. 9. (*Alcea carpinifolia*, americana frutescens, flosculis luteis, femine duplici rostro donato; Comm. Hort. v. 1. 3. t. 2.)—Leaves ovate-lanceolate, ferrated; somewhat heart-shaped at the base. Stipulas setaceous, with axillary spines. Flower-stalks simple, mostly solitary. Capsules with beaked valves.—Native of the East and West Indies, Senegal, Arabia Felix, and North America. Mr. Pursh says it is found among rubbish, and by road-sides, from Pennsylvania to Carolina, flowering in July and August. This was one of the earliest species cultivated in England, but rather for curiosity than beauty. The broader leaves principally distinguish it from the former, for their flowers are nearly similar. The root is annual or biennial.

*S. hispida.* Hispid Sida. Pursh n. 2.—“Rough with bristly hairs. Leaves lanceolate, ferrated. Flower-stalks axillary, the length of the footstalks. Outer calyx thread-shaped.”—Described by the above author, from the herbarium of Mr. Lyon, who is said to have met with this plant in the sandy plains of Georgia in North America. The flowers are yellow. If they have really an external calyx, the plant can be no *Sida*; but perhaps a simple setaceous bractea is all that is meant by the above definition. We have seen no specimen.

*S. carpinifolia.* Hornbeam-leaved Sida. Linn. Suppl. 307. Willd. n. 8. Ait. n. 3. Jacq. Ic. Rar. t. 135. Cavan. Diff. 274. t. 134. f. 1.—Leaves ovate-oblong, smooth, closely ferrated. Stalks axillary, about four-flowered. Capsule with beaked valves.—Mr. Maillon met with this shrub in the garden of a Franciscan convent, in Madeira, and sent it to Kew garden in 1774, where it is treated as a green-house plant, flowering most part of the summer. The native country has not been ascertained. The branches are hairy, spreading, like the leaves, in two directions. The latter are two or three inches long, and nearly half as broad, smooth, with crowded, acute, somewhat unequal, or doubled, ferratures, each tipped with a brittle, as in the genus *Carpinus*. Calyx smooth. Petals yellow, oblique, and partly notched. Capsule of eight cells, each having two spinous beaks. *S. planicaulis*, Cavan.

Diff. 24. t. 3. f. 11, is acknowledged by that writer himself to be the same plant in a young or imperfect condition.

*S. maculata.* Spotted-flowered Sida. Cavan. Diff. 20. t. 3. f. 7. Willd. n. 12.—Leaves ovate, obtuse, ferrated, downy. Flowers axillary, solitary; racemose at the ends of the branches. Capsule with beaked valves.—Native of Hispaniola. The stem is woody and downy. Lower leaves orbicular; upper ovate, abrupt, with a terminal point. Stipulas awl-shaped, erect, downy. Flower-stalks with a joint. Calyx villous. Corolla large, yellow, with a reddish spot on the base of each petal. Capsule of nine cells.

*S. suberosa.* Corky Sida. L'Herit. Stirp. 113. t. 54. Willd. n. 13. Ait. n. 4.—Leaves ovate, strongly ferrated, hairy. Stalks axillary, single-flowered, twice the length of the footstalks. Capsule with beaked valves. Stem corky at the base.—Native of Hispaniola. Introduced to the stoves at Kew in 1798, by sir Jussly Green, bart., but it has not yet flowered. The stem is one or two feet high, branched, the bark of the lower part corky, and full of fissures; branches hairy. Leaves more oval than in *S. carpinifolia*, pale and hairy. Flowers an inch broad, orange-coloured, with a purple central ring, their stalks and calyx hairy. Capsule small, of nine, slightly connected, cells. The corky bark, which L'Heritier compares to that of *Passiflora suberosa*, is supposed peculiar to the present species.

SECT. 2. *Leaves wedge-shaped at the base.*

*S. rhombifolia.* Rhomb-leaved Sida. Linn. Sp. Pl. 961. Willd. n. 18. Ait. n. 5. Pursh n. 3. Cavan. Diff. 23 and 48. t. 3. f. 12. (*Malvinda unicornis*, folio rhomboide, perennis; Dill. Elth. 216. t. 172. f. 212.)—Leaves oblong-lanceolate, acute, ferrated; wedge-shaped and entire at the base. Flower-stalks shorter than the leaves. Stipulas setaceous, with axillary spines.—Native of both Indies and of North America. Cultivated in curious stoves, where it blossoms in summer; but the small yellow flowers have less beauty to boast than most of the preceding, with which the plant agrees in habit, except the tapering entire base of its leaves, whose under side is a little glaucous.

*S. ciliaris.* Ciliated Sida. Linn. Sp. Pl. 961. Willd. n. 22. Ait. n. 7. Cavan. Diff. 21. t. 3. f. 9, and 275. t. 127. f. 2. (*Malva minor lupina*, betonica folio, flore coccineo, femibus asperis; Sloane Jam. v. 1. 217. t. 137. f. 2.)—Leaves oval, abrupt, ferrated; entire and somewhat wedge-shaped at the base. Stipulas linear, fringed, longer than the solitary, nearly sessile, flowers. Capsules prickly, not beaked.—Native of dry grassy places in Jamaica, and other parts of the West Indies, flowering after rains. A small, procumbent, rather shrubby species, whose leaves are scarcely an inch in length, and whose long fringed stipulas are very remarkable. The flowers are crimson. Seeds, as well as capsules, rough with minute hairs.

SECT. 3. *Leaves heart-shaped, entire, or nearly so.*

*S. periplocifolia.* Great Bind-weed-leaved Sida. Linn. Sp. Pl. 962. Willd. n. 23. Ait. n. 8. Cavan. Diff. 26. t. 5. f. 2. (*Abutilon periplocæ acutioris folio, fructu stellato*; Dill. Elth. 4. t. 3.)—Leaves heart-shaped, entire; elongated at the point; downy beneath. Flower-stalks axillary and terminal, somewhat panicled, much longer than the footstalks. Capsule with five awned cells.—Native of both Indies; long known in our gardens, where it proves annual or biennial only, even in the stove, flowering in summer. Dillenius suspects it to be perennial and shrubby in its native country. The stem with us is three or four feet high. The entire pale or hoary leaves bear some resemblance to those of *Cynanchum acutum*, though

though more elongated. This last plant being reckoned a *Periploca* by Tournefort and Dillenius, caused the above specific name. The *flowers* are yellowish, small, and fugacious, opening in bright sunshine only.

*S. nudiflora*. Naked-flowered Sida. L'Herit. Stirp. 123. t. 59, double. Willd. n. 26. Ait. n. 10. (*S. periplocifolia* β; Linn. Sp. Pl. 963. *S. stellata*; Cavan. Diss. 27 and 349. t. 5. f. 4. *Abutilon ampliflimum* folio, caule villoso; Plum. Ic. 2. t. 3.)—Leaves roundish-heart-shaped, pointed, obscurely crenate; downy beneath. Panicle terminal, racemose, leafless. Capsules without awns.—Native of Peru and the West Indies. Cultivated by Miller in 1731. Linnæus confounded this with the last, from which it differs in being a more handsome plant, with larger more copious *flowers*, rounder *leaves*, whose edges are scarcely ever entire, but minutely crenate; and *capsules* of five, six, or seven cells, pointed, but destitute of awns.

SECT. 4. *Leaves heart-shaped, indented. Stalks single-flowered.*

*S. triquetra*. Triangular-stalked Sida. Linn. Sp. Pl. 962. Willd. n. 27. Ait. n. 11. Jacq. Hort. Vind. v. 2. 54. t. 118. Cavan. Diss. 26. t. 5. f. 1.—Leaves heart-shaped, pointed, finely serrated. Flower-stalks somewhat racemose. Capsule abrupt, without awns. Branches triangular.—Native of the West Indies. Sent to Kew by professor Jacquin, its original discoverer, in 1775. This is considerably allied to the last in habit, though differing essentially in the characters here indicated. The primary *flower-stalks* are indeed solitary and axillary, but the greater part are racemose and leafless. *Flowers* small, yellow, with a purple eye. *Capsules* of five close, elongated, parallel lobes, abrupt at the summit, each lobe, or cell, pointed, but not awned.

*S. patens*. Spreading Sida. Andr. Repof. t. 571. Ait. n. 13.—Leaves heart-shaped, pointed, deeply serrated. Flower-stalks hairy, solitary, much longer than the footstalks. Capsule of five separate, taper-pointed cells.—The seeds of this fine new species were brought by Mr. Salt from Abyssinia, and plants were raised from them by lord viscount Valentia, in 1806. It flowers in the stove from July to September, and is biennial. The *branches* are round, and slightly hairy, like all the *stalks*, and the large, slender-pointed *leaves*, whose margins are deeply and acutely serrated. *Flowers* near two inches wide, yellow speckled with orange; their *petals* spreading and undulated. Cells of the *capsule* distinct almost to the very base, near an inch long, ovate, tapering gradually to a point, each containing four or five seeds.

*S. crispata*. Bladder Sida. Linn. Sp. Pl. 964. Willd. n. 40. Ait. n. 16. Pursh n. 4. Cavan. Diss. 30. t. 7. f. 1. and 275. t. 135. f. 2. (*Abutilon americanum*, fructu tubrotundo pendulo, e capsulis vesicariis crispis conflato; Mart. Cent. 29. t. 29. *A. vesicarium crispum*, floribus melius parvis; Diss. Eith. 6. t. 5. *A. aliud vesicarium*, flore luteo, minus; Plum. Ic. 15. t. 25\*.)—Leaves heart-shaped, pointed, crenate, downy. Flower-stalks solitary; deflexed when in fruit. Capsule of numerous, inflated, membranous, undulated cells.—Native of the Bahama islands, and the sea-coast of Carolina, flowering from July to September. An annual species, often seen in curious gardens, and remarkable for the bladderly pendulous *fruit*, of many tumid cells, with undulating furrows between. The *flowers* are small and white, on long, slender, simple, axillary stalks.

*S. sylvatica*. Tawny-flowered Sida. Cavan. Diss. 56 and 276. t. 133. f. 2. Willd. n. 42.—Leaves heart-shaped, taper-pointed, crenate, finely downy. Flower-

stalks axillary, aggregate, single-flowered, much longer than the footstalks. Capsules orbicular, of numerous abrupt cells.—Gathered by Dombey, in woods near the river Maragnon, in Peru. This fine species, not noticed in the Hortus Kewensis, flowered in Mr. Cooper's stove at Norwich, in November, 1811. We have also a Peruvian specimen, unnamed, from the late M. L'Heritier. The stem is eight or ten feet high, with numerous, round, downy, leafy branches. *Leaves* stalked, roundish-heart-shaped, with a long taper point, finely crenate throughout, five or seven-ribbed, clothed on both sides with soft, velvet-like, dense pubescence; rather paler beneath; the lower ones a span or more in length, and about half as much in breadth; upper much smaller and narrower, with shorter *footstalks*. *Flower-stalks* two, three, or four together, from the bosoms of the upper leaves, and about half their length, equal, erect, single-flowered, downy, jointed near the top, but without *bracteas*. *Calyx* covered with dense starry down. *Corolla* spreading about an inch and a half, of a peculiar pale brownish-orange, or bright cinnamon colour, very elegant, though not gaudy. *Capsule*, according to Cavanius, globose, concave in the middle, downy, of from thirty to thirty-six close, compressed, abrupt, unawned, single-seeded cells.

*S. arborea*. Great-flowered Sida. Linn. Suppl. 307. Willd. n. 43. Ait. n. 17. L'Herit. Stirp. 131. t. 63. (*S. peruviana*; Cavan. Diss. 36. t. 7. f. 8, and 276. t. 130.)—Leaves orbicular, heart-shaped, crenate, finely downy, with short points. Flower-stalks axillary, solitary, single-flowered, longer than the footstalks. Capsules orbicular, of numerous abrupt cells.—Native of Peru. A green-house rather than a stove-plant, both at Paris and London, flowering in the latter part of summer. This is much larger in all its parts than the foregoing, to which it is, in many respects, nearly allied. The *leaves* however differ in their short points, greater breadth, and more orbicular form, the lobes at their base folding over each other, so as to give the leaf a peltate aspect. The *footstalks* are six inches long in the lower leaves, two or three in the upper. From the bosoms of the latter proceed the *flower-stalks*, twice the length of their corresponding footstalks, always solitary, as far as we have observed, though Willdenow says they are in pairs. We suspect he confounded this species and the last. The *flowers* are full twice the size of *S. sylvatica*, and of a pale sulphur-colour, or yellowish-white.

*S. Abutilon*. Broad-leaved Yellow Sida. Linn. Sp. Pl. 963. Willd. n. 47. Ait. n. 21. (*Althæa altera*, five *Abutilon*; Camer. Epit. 668. *A. latea*; Ger. Em. 935. *Abutilon Avicennæ*; Besl. Hort. Eyf. adliv. ord. 6. t. 10. f. 1.)—Leaves roundish-heart-shaped, pointed, toothed, downy. Flower-stalks axillary, solitary, shorter than the footstalks. Capsules orbicular, of numerous, abrupt, double-beaked cells.—Native of both Indies; long cultivated in the gardens of Europe, and partly naturalized in the warmer parts, so that Haller admits it as a Swiss plant, under his n. 1075. Gerard raised it every year, from Spanish or Italian seeds; for he says it hardly ripened any in his garden, not flowering till September. The *root* is annual. *Stem* much branched. *Leaves* not unlike the *arborea* in shape, but more pointed, more coarsely notched, often obtusely lobed, and less softly pubescent. *Flowers* yellow, not an inch wide, solitary, except that each is frequently accompanied by a young flowering branch. *Capsules* downy, with a sharp, double, incurved beak to each cell.—This, like many other old garden plants, of which no coloured plates exist, ought to be figured in periodical publications,

heations, instead of the repetitions, so justly complained of, in the generality of those works. Haller records, after Linder, that the seeds of *S. Alutylon*, taken to the amount of an ounce, have been found powerfully soporific.

SECT. 5. *Leaves heart-shaped, indented. Stalks many-flowered or racemose.*

*S. umbellata.* Umbellate Sida. Linn. Sp. Pl. 963. Willd. n. 76. Ait. n. 31. Jacq. Hort. Viind. v. 1. 22. t. 56. Cavan. Diff. 28. t. 6. f. 3, and 275. t. 129. f. 2. — Leaves roundish-heart-shaped, toothed, somewhat angular, rather downy. Stalks umbellate, axillary and panicled. Capsules with double-awned cells.—Native of the West Indies. Annual or biennial, flowering in our stoves in autumn. The leaves are light green, pliant, minutely hairy, and though soft to the touch, yet not of that velvet-like texture so remarkable in most of the preceding sections. Flowers small, yellow, five or six in each long-stalked axillary solitary umbel. The upper umbels are, many of them, unattended by leaves. The valves of the capsule have each a sharp, slender, erect beak.

*S. paniculata.* Panicled Sida. Linn. Sp. Pl. 962. Willd. n. 78. Ait. n. 32. Cavan. Diff. 16. t. 12. f. 5. Swartz Obs. 259. (*S. atro-funginea*; Jacq. Coll. v. 1. 49. Ic. Rar. t. 136. *S. capillaris*; Cavan. Diff. 10. t. 1. f. 7.)—Leaves ovate or heart-shaped, toothed, downy on both sides. Flowers panicled, with capillary stalks. Capsules rough, with double-beaked cells.—Native of calcareous rocks in Jamaica, as well as Peru and Brazil. Sir Joseph Banks is recorded as having sent it, in 1795, to Kew, where it flowers in the stove from July to September. Mr. Aiton marks this species as biennial. Jacquin describes it as an evergreen shrub, eighteen feet high, almost always in bloom. Our wild Peruvian specimens appear woody, with rough round branches. The leaves are stalked, of a roundish-ovate, partly heart-shaped figure, various in length from one to three inches, strongly serrated, clothed on both sides, but most densely beneath, with stellated pubescence. Flowers small, crimson, copious, on long, very slender, panicled stalks. Corolla more or less reflexed.

*S. terminalis.* Terminal-stalked Sida. Cavan. Diff. 29. t. 6. f. 6. t. 195. f. 2. Willd. n. 82. — Leaves heart-shaped, doubly crenate, somewhat lobed, very soft and downy. Clusters simple, somewhat corymbose, on very long, solitary, terminal stalks. Capsule hairy.—Gathered at Monte Video, by Commerçon, whose specimen is before us. The stem is shrubby, much branched, downy, apparently of rather humble growth. Leaves dependent, shorter than their footstalks, heart-shaped, bluntish, veiny, scarcely an inch long, extremely soft, their notches broad, round, and very unequal. Flower-stalks terminal, though the branches are often subsequeently elongated beyond them, solitary, simple, naked, four or five inches in length, round, downy, each bearing four or five rather large, stalked, corymbose, yellow flowers, externally purplish, with linear bractees, which soon fall off. The capsule, twice as long as the calyx, is thickly clothed with long upright hairs.—The curious reader may observe how Willdenow, without any other guide than the description and plates of Cavanilles, has altered his specific character for the worse. Willdenow terms the leaves "ovato-lanceolate" and "toothed;" for neither of which there is any foundation; but it may serve us, in any other doubtful case, to understand his phraseology, for which reason, chiefly, we here point it out.

SECT. 6. *Leaves heart-shaped, three-pointed, or angular at the base.*

*S. crassifolia.* Thick-leaved Sida. L'Herit. Stirp. 125. t. 60. Willd. n. 84. (*S. tricutpidata*; Cavan. Diff. 30.

t. 6. f. 5.)—Leaves heart-shaped, toothed, pointed, obscurely lobed, downy on both sides. Stalks solitary, single-flowered, about equal to the footstalks. Capsules with double-beaked cells, rather longer than the calyx.—Gathered in Hispaniola by Thierry de Menonville. A stove-plant at Paris, unknown in our collections. The stem is shrubby, branched, round, downy. Leaves three inches long, strongly scented, bordered with tooth-like serratures, and furnished with one or two slight lobes at each side. Flowers yellow, an inch broad, on long, simple, axillary stalks.

*S. periptera.* Shuttlecock Sida. Sims in Curt. Mag. t. 1644.—Leaves heart-shaped, serrated, pointed, downy on both sides, somewhat angular; the upper ones halberd-shaped. Panicle racemose. Petals emarginate, nearly erect, shorter than the stamens. Capsule without beaks.—Supposed to be a native of Mexico. It flowers nearly throughout the year, in the collection of John Walker, esq. of Arno's grove, Southgate; but we are not informed whether it is a greenhouse or stove-plant. The stem is tall and shrubby, with round hispid branches. Leaves green, alternate, stalked, distant; the upper ones elongated, and deeply lobed. Flowers elegant, bright scarlet, near an inch long, of a shuttlecock form, as the inversely heart-shaped, oblong petals spread but very little. The column of stamens rises considerably above them.

*S. hastata.* Halberd-leaved Mexican Sida. Willd. n. 89. Ait. n. 33. Andr. Repof. t. 588. Curt. Mag. t. 1541. (*S. cristata*  $\beta$ ; Linn. Sp. Pl. 964. *Anoda hastata*; Cavan. Diff. 38. t. 11. f. 2.)—Lower leaves heart-shaped, lobed; upper hastate. Stalks axillary, solitary, single-flowered, longer than the leaves. Petals obovate, spreading, entire. Native of Mexico. Its seeds were brought from Spain by the late marchioness of Bute. An annual or biennial stove plant, which may be raised on a hot-bed early in the spring, and planted out in the open border. It is scarcely however likely to be added to the list of tropical annuals, generally so cultivated, being much inferior in beauty to many other plants, of the Mallow tribe, that are quite hardy. Its flowers are light purplish-blue, about an inch wide, on long, straggling stalks. The divisions and shape of the leaves vary greatly. The valves of the capsule have no beaks.

*S. cristata.* Crested Sida. Linn. Sp. Pl. 964. Willd. n. 90. Curt. Mag. t. 330. (*Anoda triloba*; Cavan. Diff. 39 and 55. t. 10. f. 3.)—Leaves crenate, pointed; the lower ones angular; upper hastate. Stalks axillary, solitary, single-flowered, longer than the leaves. Petals inversely heart-shaped, thrice the length of the calyx.—Native of Mexico; long since known in our gardens. We have however ascertained the synonym of Cavanilles, by seeds received from himself, and raised by the late lady Amelia Hume, in whose stove this plant flowered in July 1806. It may probably succeed, as Mr. Curtis observes, if raised on a hot-bed and planted out in a flower-border. This is distinguished from the last by its very large crimson flowers, rendering it far more worthy of cultivation. Few plants vary more in the shape of their foliage, so that we are fatished of the *S. Dilleniana*, Willd. n. 91. Ait. n. 34, figured in Cavanilles, t. 11. f. 1, and in Dill. Hort. Elth. t. 2, being a mere variety; so little defined indeed, that we can hardly distinguish it as even such.

SECT. 7. *Leaves lobed, palmate, or compound.*

*S. triloba.* Three-lobed Cape Sida. Cavan. Diff. 11. t. 1. f. 11, very bad; and 274. t. 131. f. 1. Willd. n. 92. Thunb. Prodr. 117. Jacq. Hort. Schonbr. v. 2. 9. t. 142. —Leaves heart-shaped, toothed, with three or five lobes; the middle one longest and sharpest. Stalks axillary, solitary,

tary, single-flowered, longer than the leaves. Lobes of the capsule obtuse.—Native of the Cape of Good Hope. The stem is shrubby, much branched, widely spreading. Leaves one and a half or two inches wide. Flowers small, white, inferior in beauty to those of the *Malva fragrans* or *capensis*, to which this plant is strictly allied in habit and every character, except the want of an outer calyx.

*S. ternata*. Ternate-leaved Cape Sida. Linn. Suppl. 307. Willd. n. 93. Thunb. Prodr. 118.—“Leaves ternate; leaflets lanceolate, distantly serrated.”—Gathered by Thunberg at the Cape. We have seen no specimen; but by the above scanty information, this should seem to differ from the last much as the two Cape Mallows, just mentioned, differ from each other.

*S. pterosperma*. Wing-seeded Jagged Sida. L’Herit. Stirp. 119. t. 57. Willd. n. 94. (*S. multifida*; Cavan. Diff. 25. t. 4. f. 2.)—Leaves with three deep, obtuse, sinuated lobes. Panicle much branched. Cells of the capsule numerous, each crowned with a double membranous wing—Gathered by Dombey, in sandy ground at Lima. It was raised at Paris, but required great heat. The root is annual. Stem prostrate, much branched, a foot long, round, besprinkled with starry hairs. Leaves on long stalks, deeply divided, pinnatifid or waved, with blunt rounded lobes and segments. Flowers small, white, in terminal, paniced, rather hairy, clusters, each flower on a long stalk, and turned downwards. Capsule very peculiar, on account of the numerous, double, membranous, rounded wings, which form an orbicular crest on its summit.

*S. jatrophoides*. Physick-nut-leaved Sida. L’Herit. Stirp. 117. t. 56. Willd. n. 96. Ait. n. 35. (*S. palmata*; Cavan. Diff. 274. t. 131. f. 3. Jacq. Ic. Rar. t. 547.)—Leaves palmate, with deep, acute, pinnatifid lobes. Panicle many-flowered, hairy. Cells of the capsule without awns.—Native of Lima and Peru. Sent to Kew in 1787 by M. Thouin. An annual stove-plant, flowering in August, and distinguished by the deep lobes of its leaves, seven or more, variously and deeply sinuated, pinnatifid and cut, resembling those of the *Napaea*, to which genus we suspect this species may naturally belong; for L’Heritier speaks of the seeds as separating with difficulty from their cells. We are puzzled by his account of these cells being awned in the wild plant, but not in the cultivated one. But this difficulty may be solved by his having, like Cavanilles, originally confounded the present species with what he afterwards called *S. ricinoides*, in which the valves of the cells are strongly awned. We have a specimen of *jatrochoides* from L’Heritier himself marked *ricinoides*. Yet the two are very distinct in their foliage as well as fruit.

*SIDA*, in *Gardening*, contains plants of the exotic, tender, herbaceous, perennial kind, of which the species chiefly cultivated are; the rhomb-leaved sida (*S. rhombifolia*); the great bindweed-leaved sida (*S. periplocifolia*); the triangular-stalked sida (*S. triquetra*); the broad-leaved sida (*S. abutilon*); the white-flowered sida (*S. alba*); and the heart-leaved sida (*S. cordifolia*).

*Method of Culture*.—These plants may be increased by seeds, which should be sown upon a moderate hot-bed in the early spring, or in pots deposited in them. In the first case, when the plants have attained some growth, they should be removed to another hot-bed, and be set out four inches apart each way, or into separate pots, replunging them in the hot-bed, being shaded till they have taken new root; a large proportion of free air being admitted in fine weather, and also frequent waterings: they should afterwards be gradually hardened to bear the open air in the summer season.

Some of them may also be raised from offsets and cuttings, planted in pots in the summer season.

It may be noticed that the fourth sort is sufficiently hardy to bear the open air: the seeds should be sown where the plants are to remain, as they do not bear transplanting well. It is an annual plant.

As some of the species do not flower till the second year, of course they should be placed in the stove in the autumn, and be managed during the winter as other tender exotic plants of the same nature.

Most of these afford ornament among other potted plants in the stove, and the fourth sort in the borders and other parts of pleasure-grounds.

*SIDA*, in *Ancient Geography*, a town of Asia, in Pamphylia, upon the sea-coast, near the mouth of the river Eurymedon. Ptolemy.—Also, a town of Greece, in the Peloponnesus, which took its name from one of the daughters of Danaus, according to Pausanias.

*SIDACA*, a town of Asia Minor, in Lycia. Steph. Byz.

*SIDALA*, a town of Asia, in Armenia Major. Ptol.

*SIDAMER*, in *Geography*, a kingdom of the island of Java, on the S. coast, bounded on the W. by Bantam, on the N. by Jacatra, on the E. by Kandang Wesce, and on the S. by the sea.

*SIDASIVA*, in *Mythology*, a name of the Hindoo god Siva, the prefixed epithet being one of reverence. It is not often used, though it frequently occurs in the Siva-purana.

*SIDATSCHOW*, or *ZYDACZOW*, in *Geography*, a town of Aultrian Poland, in Galicia; 35 miles S. of Lemberg. N. lat. 49° 16'. E. long. 24° 19'.

*SIDBY*, a town of Sweden, in the province of Wafra; 15 miles S. of Christinestadt.

*SIDDAPOUR*, a town of Hindoostan, in Myfore; 10 miles S.W. of Periapatam.

*SIDDINGHAUSEN*, a town of Westphalia, in the bishopric of Paderborn; 3 miles S.S.W. of Buren.

*SIDDO*, a harbour on the W. coast of Sumatra. N. lat. 5° S'. E. long. 95° 27'.

*SIDDOW*, in *Agriculture*, a term provincially applied to peas that boil soft. It is employed in some districts, as Gloucestershire, to signify or denote such peas as boil freely, or in a ready manner, into a soft mass. Some sorts of lands only have the peculiar property or quality of raising or producing this kind, or those that possess such a capability. Upon them, therefore, those of the Charlton sort are mostly sown or planted in this intention. Soils of the calcareous description or quality are commonly capable of affording this boiling sort; but those that are of the clayey kind do not possess the same capability. This quality in pease is expressed by the terms boiling, making, and some others, in different other districts. See *PEA*.

*SIDE*, in *Ancient Geography*, a place of Asia Minor, in the Troade. Strabo.

*SIDE*, *Latus*, in *Geometry*. The *side* of a figure is a line making part of the periphery of any superficial figure. See *FIGURE*.

In triangles, the sides are also called *legs*. In a right-angled triangle, the two sides, including the right angle, are called *catheti*; and the third, the *hypotenuse*.

*Side* of a polygonal number is the number of the terms of the arithmetical progression that are summed up. See *POLYGONAL NUMBER*.

*Side* of power is what we otherwise call the *root*, or *radix*.

*SIDES* of horn-works, crown-works, double tenailles, and the like out-works, are the ramparts and parapets which

inclose them on the right and left, from the gorge to the head.

*SIDE, Right, in Conics.* See *LATUS Rectum.*

*SIDE, Transverse.* See *LATUS Transversum.*

*SIDES of a Ship,* are distinguished into the *starboard* and *larboard*; that is, into the right and left-hand side, when standing with the face towards the head of the vessel. See *STARBOARD* and *LARBOARD.*

*SIDE, Broad, in Sea Language,* is to fire all the guns on one side of the ship.

*SIDE-Wind.* See *WIND.*

*SIDE-Grafting.* See *ENGRAFTING.*

*SIDE-Lays* is a term made use of by huntfmen, when dogs are placed in the way, to be let slip at a deer, as he passes by.

*SIDE-Saddle Flower.* See *Hollow-leaved Sea LAVENDER.*

*SIDE-Cuts,* are the short lengths of canal by the sides of rivers, for condensing the navigation by mills, shallows, &c.

*SIDE-Laying Ground,* is that whose surface, as *A E L* (*Plate I. Canals, figs. 2 and 3.*) is lower on one side of the canal than on the other.

*SIDE-Locks, or Side-ponds,* are reservoirs or excavations by the side of a canal or lock, for retaining water. See *CANAL.*

*SIDE-Puddle* is often used to express the puddle-ditches, gullies or gutters that are formed like a wall within a canal-bank, for preventing breaks from the same.

*SIDELING HILLS,* in *Geography,* a range of hills in America, on the N.W. part of the state of Maryland.

*SIDENA,* in *Antient Geography,* a town of Asia Minor, in Lycia. Steph. Byz.

*SIDENA, or Sidona,* a very fertile country of Asia, on the sea-coast, in the kingdom of Pontus, in which, according to Strabo, were some strong places, besides a town of the same name.—Also, a town of Asia Minor, in the Troade, upon the Graucius; which was ruined in the time of Strabo.

*SIDENI,* a people of Germany, who occupied the banks of the Oder.—Also, a people of Arabia Felix. Ptol.—Also, a people of the Cappadocian Pontus, who inhabited the country of Sidena. Pliny.

*SIDENI Sinus,* a gulf of Asia Minor, upon the Thraecian Bosphorus, near the Euxine sea. This gulf was formed by the promontory Ancyreum and by that of Pflonion.

*SIDENSIO,* in *Geography,* a town of Sweden, in Angermanland; 40 miles N. of Hernofand.

*SIDEPATTY,* a town of Bengal; 12 miles N.W. of Midnapour.

*SIDERATIO,* in *Medicine,* from *sidus,* a planet, because violent and sudden maladies were ascribed to the influence of the stars, a term which has been applied to several diseases of that character. It has been principally used to signify *apoplexy,* or a sudden *palsy*; but it has been applied by others to *mortification,* or *spbacelus* of a limb; and by some to *erysipelas* of a limb, which is vulgarly called a *bliss.*

*SIDERATION,* the blasting or blighting of trees, plants, &c. by eastern winds, excessive heat, drought, or the like causes. See *BLIGHT.*

*SIDERIA,* in *Natural History,* the name of a genus of crystal. The word is derived from the Greek *σίδηρος, iron,* and is used to express crystals altered in their figure by particles of that metal. These are of a rhomboidal form, composed only of six planes.

Of this genus there are four known species. 1. A colourless, pellucid, and thin one, found in considerable quantities among the iron ores of the forest of Dean, in Gloucester-

tershire, and in other the like places. 2. A dull, thick, and brown one, not uncommon in the same places with the former. And, 3. A black and very glossy kind, a fossil of very great beauty, found in the same place with the others, as also in Leicestershire and Suffex. Hill.

*SIDERIAL YEAR.* See *YEAR.*

*SIDERIAL Day* is the time in which any star revolves from the meridian to the meridian again; viz. 23 hours, 56 minutes, 4 seconds, 6 thirds of mean solar time. There are 366 siderial days in a year, or in the time of 365 diurnal revolutions of the sun. The first column of the following table is the number of revolutions of the stars; the others next are the times in which these revolutions are made, as shewn by a well-regulated clock; and those on the right hand shew the daily accelerations of the stars, that is, how much any star gains upon the time shewn by such a clock, in each revolution.

Revolutions of the Stars.	Times in which these Revolutions are made.						Accelerations of the Stars.

This table will not differ the 279,936,000,000th part of a second of time.

If the equinoctial points were at rest in the heavens, there would be exactly 366 revolutions of the stars from the meridian.

dian to the meridian again in 365 days. But the equinoctial points go backward with respect to the stars, at the rate of fifty seconds of a degree in a Julian year; which causeth the stars to have an apparent progressive motion eastward fifty seconds in that time. And, as the sun's mean motion in the ecliptic is only 11 signs 29 degrees 48 minutes 40 seconds 15 thirds, in 365 days, it is plain, that at the end of that time he will be 14 minutes 19 seconds 45 thirds short of that point of the ecliptic from which he set out at the beginning; and the stars will be advanced 50 seconds of a degree with respect to that point.

Consequently, if the sun's centre be on the meridian with any star on any given day of the year, that star will be  $14' 19'' 45''' + 50''$ , or  $15' 9'' 45'''$  east of the sun's centre, on the 365th day afterward, when the sun's centre is on the meridian; and therefore that star will not come to the meridian on that day till the sun's centre has passed it by 1 minute 0 second 38 thirds 57 fourths of mean solar time; for the sun takes so much time to go through an arc of  $15' 9'' 45'''$ ; and then, in 365 days 0 hour 1 minute 0 second 38 thirds 57 fourths, the star will have just completed its 366th revolution to the meridian.

This table was calculated by Mr. Ferguson; and it is the only table of the kind in which the recession of the equinoctial points has been taken into the calculation.

**SIDERITE**, in *Minerology*, a name given by Bergman to a supposed peculiar metallic substance, which is the principal cause of the brittleness of certain kinds of bar iron. It has since been discovered to be phosphate of iron.

**SIDERITES**, a name which some authors give to the load-stone. See **MAGNET**.

**SIDERITIS**, in *Botany*, supposed to be the *σίδηριτις* of the Greeks, of which Dioscorides describes three species, all celebrated for staunching blood, and healing wounds. The first quality they might very well possess, being, according to his account, rough herbs, akin to *Marrubium*, in which also there might be somewhat of an astringent or tonic quality. They answer indeed to the general idea of the genus to which modern botanists have applied the name, whose etymology is to be sought in *σίδηρος*, iron; but whether it alludes to that metal as the cause of wounds, to the rusty colour of the flowers, as De Theis imagines, or to any other circumstance, nothing but conjecture can be offered.—Linn. Gen. 290. Schreb. 387. Willd. Sp. Pl. v. 3. 63. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 384. Sm. Prodr. Fl. Græc. Sibth. v. 1. 400. Juss. 113. Tourn. t. 90. Lamarck Illustr. t. 505.—Class and order, *Didynamia Gymnospermia*. Nat. Ord. *Perticillata*, Linn. *Labiata*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, oblong, cut nearly half way down into five acute, almost equal, segments. *Cor.* of one petal, nearly equal; tube cylindrical, oblong; throat oblong, somewhat cylindrical; upper lip erect, narrow, divided; lower in three segments, of which the lateral ones are most acute, and scarcely so large as the upper lip, the middle one roundish. *Stam.* Filaments four, within the tube of the corolla, and shorter than the throat, two of them smaller than the rest; anthers roundish, two of them with two distinct lobes. *Pist.* Germen four-cleft; style thread-shaped, rather longer than the stamens; stigmas two; the uppermost cylindrical, concave, abrupt; the lower membranous, shortest, sheathing the other. *Peric.* none, the seeds being lodged in the base of the calyx. *Seeds* four.

Ess. Ch. Calyx five-cleft. Corolla ringent; its upper lip erect, divided; lower deeply three-cleft. Stamens

within the tube of the corolla. One stigma shorter, embracing the other.

1. *S. canariensis*. Canary Iron-wort, or Sage-tree. Linn. Sp. Pl. 801. Ait. n. 1. Jacq. Hort. Vind. v. 3. 18. t. 30. (*Stachys amplifolius verbasci foliis, floribus albis, &c.*; Pluk. Almag. 356. Phyt. t. 322. f. 4.)—Shrubby and villous. Leaves oblong-heart-shaped, acute, stalked. Spikes simple, whorled, drooping before flowering. Branches spreading. Calyx awned.—Native of Madeira, and the Canary islands. Cultivated in our greenhouses 120 years ago, and still preserved in general collections, flowering throughout the summer. The stem and stalks are clothed with soft, dense, white, velvet-like pubescence. Leaves green above, elegantly edged with white, finely crenate, rather flaggy; more thickly clothed beneath. Whorls dense, numerous, accompanied by diminished leaves, so as to form a long spike, drooping while young, but destitute of proper bractæ. Flowers very numerous, white, with a wide orbicular mouth, and shortish limb, whose upper segment hardly answers to the generic character, being notched, but not cloven in the middle.

2. *S. canalicans*. Mullein-leaved Iron-wort. Ait. n. 2. Willd. n. 2; excluding the synonym.—Shrubby and downy. Leaves densely downy, ovato-lanceolate, taper-pointed; heart-shaped at the base; snow-white beneath. Spikes compound. Whorls remote, each of about eight flowers. Calyx obtuse, pointless.—Native of Madeira; long known in the gardens of England, as well as Holland; flowering from April to July, and sheltered in the greenhouse in winter, with moderate supplies of water. Akin to the preceding, with which Linnæus confounded it; but differing in the peculiar dense snow-white clothing of the leaves, which almost resemble thick white leather. The flowers are larger, and fewer, with an obtuse, very woolly, calyx, destitute of awns, and grow in compound, whorled, leafy spikes. The inflorescence is so different from Commelin's figure, cited by Aiton and Willdenow, that we rather follow Linnæus in applying that synonym to the following species; though not quite without a suspicion of its really belonging to *S. canariensis*.

3. *S. cretica*. Cretan Iron-wort. Linn. Sp. Pl. 801, excluding the reference to Tournefort. Willd. n. 3. (*Stachys canariensis frutescens, verbasci foliis; Commel. Hort. v. 2. 197. t. 99?*)—Shrubby and downy. Leaves densely downy, heart-shaped, bluntish, broadly crenate, on long stalks; snow-white beneath. Spikes simple, whorled. Calyx obtuse, pointless.—Native of Crete and Greece. This has the very dense white pubescence of the last species, but differs in its larger, blunter, more strongly crenate leaves, and especially its solitary unbranched leafless spikes. The whorls consist each of eight or more flowers, whose calyx, though less woolly, nearly agrees with the preceding, being totally unlike the spinous-pointed calyx of *S. canariensis*. If Commelin's plate had been executed with any care, this circumstance would have determined his synonym, which certainly belongs either to our first or third species, and not to the second.

4. *S. syriaca*. Syrian Iron-wort. Linn. Sp. Pl. 801. Willd. n. 7. Ait. n. 6. Sm. Fl. Græc. Sibth. t. 550, unpublished. (*S. cretica tomentosa candidissima, flore luteo; Tourn. Cor. 12. Stachys; Ger. Em. 695. S. lychnoides incana angustifolia, flore aureo, italica; Barrel. Ic. t. 1187.*)—Shrubby, clothed with woolly down. Leaves elliptic-lanceolate, nearly entire. Whorls axillary, many-flowered. Calyx acute, without awns.—Native of Italy, Crete, and various parts of the Levant. The root is perennial

## SIDERITIS.

ennial and woody. *Stems* erect, mostly simple, herbaceous, a foot high, clothed, like the whole of the herbage, with long, soft, silky, dense, white wool. The radical and lower *stem-leaves* are obovate, or elliptic-lanceolate, obscurely crenate; those which accompany the flowers are generally much shorter, ovate, and acute; sometimes they nearly resemble the rest of the foliage, evincing that they are not *bracteas*, as some esteem them, but real leaves. *Whorls* about eight, a little distant, each of six bright yellow *flowers*. *Calyx* obovate, densely woolly, with five sharp teeth, but no awns or points. *Corolla* twice as long, contracted at the mouth, downy externally, its segments acute, all entire.

5. *S. taurica*. Tartarian Iron-wort. Willd. n. 8. ("S. Syriaca; Pallas Nov. Act. Petrop. v. 10. 312.")—Somewhat shrubby, downy. Leaves lanceolate, crenate. Whorls crowded. Floral leaves heart-shaped, pointed, reticulated with elevated veins.—Native of Tartary. The *branches* are a foot long, subdivided, clothed with white down. Radical *leaves* stalked, *stem-leaves* sessile, all crenate, rugged with veins, and covered with fine woolliness; the floral ones roundish-ovate, pointed, ribbed, reticulated, shorter than the *calyces*; woolly, like the other leaves, till the flowers are past, when they become nearly smooth, except the edges. *Corolla* yellow. Willd.

6. *S. difflans*. Distant-whorled Iron-wort. Willd. n. 9.—"Somewhat shrubby, hoary. Leaves lanceolate, acute, entire. Whorls distant. Floral leaves heart-shaped, sharp-pointed, reticulated with elevated veins."—Supposed to be a native of the Levant. Willdenow obtained it from some old herbarium, with the name of *Sideritis foliis conjugatis amplexicaulis rigidis*. He describes it as like the former, but different, having acute, entire, less downy *leaves*, the *stem* alone being villous. *Whorls* very distant, accompanied by nearly smooth leaves, with sharp points. Tube of the *corolla* longer than the *calyx*; the middle segment of its lower lip obtuse, but not emarginate. We are unacquainted with any thing answering to this description.

7. *S. perfoliata*. Perfoliate Iron-wort. Linn. Sp. Pl. 802. Willd. n. 10. Ait. n. 7. Prodr. Fl. Græc. n. 1330. (*S. orientalis*, phlemidis folio; Tourn. Cor. 12?)—Herbaceous, rough with bristly hairs. Upper leaves ovato-lanceolate, obscurely toothed, clasping the stem; floral ones heart-shaped, sharp-pointed, reticulated, fringed.—Native of the Levant. Dr. Sibthorp gathered it in some part of Greece, or the neighbouring islands, but omitted to mark the precise spot. No figure is extant of this species. The *herbage* is green, hairy, and bristly, not downy. *Leaves* reticulated with copious veins; the floral ones crowded, short, and broad, with spinous points, their disk pale, and semi-pellucid. *Flowers* six in a whorl. *Calyx* tubular, round, without angles, glandular and hairy; its teeth long, erect, ribbed, spinous. Linnæus says the *corolla* is white, with some reddish veins.

8. *S. ciliata*. Fringed Japan Iron-wort. Thunb. Jap. 245. Willd. n. 11.—Herbaceous, villous. Leaves stalked, ovate, serrated, dotted; the floral ones orbicular, ribbed, fringed.—Native of Japan. *Stem* a foot high, or more, square, erect, branched. *Leaves* hardly an inch long, acute; pale beneath; marked on the upper side with depressed dots. *Footstalks* rather shorter than the leaves. *Spikes* terminal (whorled?) lanceolate, erect, a finger's length. *Floral leaves* imbricated, pointed, not spinous. Thunb.

9. *S. montana*. Mountain Iron-wort. Linn. Sp. Pl. 802. Willd. n. 4. Ait. n. 3. Jacq. Austr. v. 5. 16.

t. 434. Sm. Fl. Græc. Sibth. t. 551, unpublished. (*S. montana*, parvo flore nigro-purpureo; Column. Euphr. 198. t. 196.)—Herbaceous, decumbent, hairy. Leaves deflexed, spinous-pointed. *Calyx*-teeth spreading, spinous, nearly uniform.—Native of Italy and the Levant. A hardy annual, cultivated by Miller in Chelsea garden, where it still springs up spontaneously every year, flowering in June and July. The *stem* is branched from the bottom, hairy, rather rigid, a foot long, diffuse, clothed all the way up with ovate, concave, deflexed, slightly notched, green, hairy *leaves*, each accompanied by a whorl of six *flowers*. The *calyx* is tubular, very hairy, except its lip, which spreads in two divisions; the upper three-lobed, with three spinous teeth; the lower deeply divided, rather narrower, with two; mouth hairy. *Corolla* with a yellow slender tube, the length of the *calyx*; limb various, sometimes very small, yellow, bordered with brown on all sides; sometimes, as in our garden plants, and in Dr. Sibthorp's Greek specimens, the upper lip only is small and brown, the lower dilated, yellow, obtusely three-lobed. This does not at all answer to the figure and description of *Columna*. We are not without a suspicion of two species being here confounded, and yet we are not able to trace a permanent distinction between any of the specimens we have seen.

10. *S. romana*. Simple-beaked Iron-wort. Linn. Sp. Pl. 802. Willd. n. 6. Ait. n. 5. Cavan. Ic. v. 2. 69. t. 187. Sm. Fl. Græc. Sibth. t. 552, unpublished. (*Sideritis* genus spinosis verticillis; Bauh. Hist. v. 3. 428.)—Herbaceous, decumbent, hairy. *Calyx*-teeth spinous; the uppermost largest, solitary, ovate.—Gathered by Cherler first near Rome, whence the specific name. It has however been found in fields and waste ground in many other parts of the south of Europe. Dr. Sibthorp observed this plant to be common in Greece and the isles of the Archipelago, and we have suspected it might be the real *Sideritis* of Dioscorides, to whose description, as far as any thing can thence be determined, it answers well. The *habit* of the plant is much like the last, but the *leaves* are more notched, shorter and broader. Tube and upper lip of the *corolla* pale red; lower lip white, dilated as in the larger-flowered variety of the preceding. The most striking difference is found in the *calyx*, whose upper lip is erect, large, and ovate, the lower of four slender teeth, spreading downward.

11. *S. lanata*. Dark-flowered Iron-wort. Linn. Sp. Pl. 804. Willd. n. 20. Prodr. Fl. Græc. n. 1333. (*S. elegans*; Murray in Comm. Gott. for 1778. 92. t. 4. Willd. n. 5. *S. nigricans*; Lamarck Dict. v. 2. 168.)—Herbaceous, diffuse, hairy. Leaves elliptical, obtuse, crenate, without spines. *Calyx*-teeth spreading, spinous, hairy, nearly uniform.—Native of Egypt, Caria, and Palestine. Murray first described it at Gottingen, from garden specimens, without knowing whence they came. Nor was he blameable for not discovering his plant to be *S. lanata* of Linnæus, whose specific character, made from a starved wild specimen, is calculated to mislead those who had no other guide. Yet the great Swedish botanist appears, by his herbarium, to have rightly understood the cultivated plant of Murray, of which he possessed a very old and luxuriant mortal, apparently from some Dutch collection. This species is undoubtedly most akin to *montana* and *romana*, nor has it any real *bracteas*. The *whorls*, as in those, are all axillary, six-flowered. *Calyx* invested all over with long silky hairs, its teeth tipped with spines, the upper one rather longer than the others, but all nearly equal in breadth. *Corolla* with a white tube; the front of the limb dark purplish-brown, nearly black, of a very striking appearance; its

its upper segment cloven; lower in three rounded lobes. The *leaves* vary greatly in size, but are rounded, pointless, copiously and distinctly crenate; the lower ones stalked.

12. *S. incana*. Lavender-leaved Iron-wort. Linn. Sp. Pl. 802. Willd. n. 12. Ait. n. 8. Cavan. Ic. v. 2. 69. t. 186. (*Hyssopus montana verticillata major*; Barrel. Ic. t. 239. *H. verticillata minor*; Boec. Mus. 77. t. 67. f. 2, the name transposed from t. 68. f. 2.)—Somewhat shrubby, downy, hoary. Leaves linear-lanceolate, entire. Bractæas ovate, palmate, with many spinous teeth.—Native of Spain. Cultivated by Miller in 1752, being tolerably hardy, flowering in July and August. The *habit* of the plant is much like Lavender. *Whorls* distant, four or five in each spike, with a pair of close, firm, ribbed, shortish bractæas, cut into many spinous segments, under every whorl. *Calyx* clothed with white cottony down; its teeth erect, spinous, nearly equal. *Corolla* twice as long as the calyx, yellow, white, or pale blue; both its lips dilated and spreading.

*S. virgata*, Desfont. Atlant. v. 2. 15, 125. Willd. n. 13, seems the very same plant, not even a variety. We venture to remove Barrelier's synonym, cited by Desfontaines, to the following, as Willdenow has done.

13. *S. glauca*. Slender Glaucous Iron-wort. Cavan. Ic. v. 2. 68. t. 185. Willd. n. 14. (*Hyssopus montana verticillata minor*; Barrel. Ic. t. 240.)—Herbaceous, glaucous, somewhat downy. Leaves linear-spatulate, entire. Bractæas wedge-shaped, palmate, spinous.—Native of Valencia. Very nearly akin to the last, but said to be herbaceous, and less downy. The *flowers* appear to be smaller, and the bractæas are considerably so. It may nevertheless be merely a variety.

14. *S. hyssopifolia*. Hyssop-leaved Iron-wort. Linn. Sp. Pl. 803. Willd. n. 15. Ait. n. 9. (*S. alpina*; Villars Dauph. v. 2. 373. *S. alpina hyssopifolia*; Ger. Em. 696. *S. montana*, &c.; Barrel. Ic. t. 171. 172.)—Leaves lanceolate, smooth, nearly entire. Bractæas heart-shaped, with spinous teeth, as long as the calyx.—Native of the mountains of Switzerland, Dauphiny, Italy, and the Pyrenées. Cultivated by Gerarde in his garden, and still preserved in curious or general collections, being a hardy perennial, flowering throughout the summer and autumn. The *stems* are somewhat woody, throwing up many leafy squarish branches, a span high, hairy at the two opposite sides, in lines crossing each other at every joint. *Leaves* numerous, opposite, stalked, green, elliptic-lanceolate, two or three of the upper ones only occasionally toothed. *Whorls* more or less crowded into an ovate or oblong, solitary, terminal spike, each whorl accompanied by two broad, reticulated, hairy bractæas, with strong spinous serratures. *Calyx-teeth* long, spinous, erect, nearly equal. *Corolla* straw-coloured, with two dilated lips, longer than the calyx.

15. *S. scordioides*. Scollop-leaved Iron-wort. Linn. Sp. Pl. 803. Willd. n. 16. Ait. n. 10. Villars Dauph. v. 2. 374. Ger. Em. 696. (*S. montana scordioides glabra*; Barrel. Ic. t. 343.)—Leaves lanceolate, somewhat hairy, distantly toothed. Bractæas ovate, with spinous teeth, as long as the calyx.—Native of the mountains of Switzerland and France. Very nearly resembling the last in every essential character, especially the hairy lines on the *stem*, though usually a larger plant, with more constantly toothed *leaves*. The degree of hairiness on the leaves is somewhat variable.

16. *S. spinosa*. Spinous-leaved Iron-wort. Vahl. Symb. v. 1. 41. Willd. n. 17. Lamarek Dict. v. 2. 169. (*S. subspinosa*; Cavan. Ic. v. 3. 5. t. 209.)—Leaves lanceolate, pointed, with strong spinous teeth, as well as the reticulated heart-shaped bractæas. Stem equally hairy on all

sides.—Native of mountains in Spain, flowering in June. We received it from the late abbé Cavanilles. The habit of the plant, as well as its *inflorescence* and *flowers*, all seem to agree with the two last; but the sharpness of the *leaves*, and their strong spinous teeth, as well as the more strongly reticulated, and deeply cut, bractæas, indicate an essential difference, confirmed perhaps by the pubescence of the *stem*, which is generally, though sparingly, diffused, not collected into two dense opposite lines. The *leaves* moreover are very strongly ribbed.

17. *S. hirsuta*. Hairy Procumbent Iron-wort. Linn. Sp. Pl. 803. Willd. n. 18. Ait. n. 11. (*S. tertia*; Clus. Hist. v. 2. 40. Tetralut herbariorum; Lob. Ic. 523. Herba judaica Lobelii; Ger. Em. 690.)—Leaves oblong, obtuse, strongly toothed. Bractæas with spinous teeth. Stems hairy all round, decumbent at the base.—Native of Spain, Italy, and the south of France.—Very much akin to the three last in its *flowers*, bractæas, &c. but more hairy. The form and teeth of the *leaves* agree with *scordioides*, a hairy variety of which, we suspect, is sometimes taken for the true *hirsuta*. The latter however appears essentially to differ, in having the copious hairiness of its *stem* equally dispersed all round, not collected into decussating lines. The *whorls* vary much in being crowded or remote, and are very hairy. The wooden cut cited above, which is the same in all the three authors, does not well represent the *inflorescence*, nor distinguish the bractæas from the *leaves*. It seems taken from an axillary-whorled species, like *montana*, *romana*, &c.

18. *S. ovata*. Ovate Peruvian Iron-wort. Cavan. Ic. v. 1. 36. t. 48. Willd. n. 19.—Herbaceous, downy. Leaves stalked, elliptical, obtuse, crenate. Whorls crowded. Bractæas ovate, spinous-toothed, imbricated in four rows.—Native of Peru. It flowered in the gardens of Madrid, in July. The *root* is fibrous and perennial. *Stems* scarcely a foot high, square, slightly hairy. *Leaves* about two inches long, on stalks about the same length; rough on the upper side, with hairs proceeding from minute tubercles; smooth and shining beneath. *Spike* solitary, terminal, about three inches long, quadrangular. Bractæas crowded, in four rows, ovate, acute, rigid, spreading, beset with strong spinous serratures. *Flowers* six in a whorl, three to each bractea. *Calyx* with five slender, sharp, nearly equal teeth. *Corolla* yellowish-white; its upper lip entire, lower three-lobed, the middle lobe three-cleft.

SIDERIS, in *Gardening*, contains plants of the under-shrubby, and shrubby exotic kind, of which the species cultivated are, the Canary iron-wort (*S. canariensis*); the Cretan iron wort (*S. cretica*); and the sage-leaved iron-wort (*S. tyrica*). But there are other species that may be cultivated for the sake of variety.

*Method of Culture*.—These plants may be increased by seeds, cuttings, and layers. The seeds should be sown in pots in the spring, plunging them in a moderate hot-bed: when the plants have had some growth, they should be removed into separate small pots, filled with light mellow mould, being afterwards treated as other shrubby greenhouse plants. The cuttings and layers may be planted out or laid down in the summer season, and when sufficiently rooted managed as the other sorts. Also, the third sort may be increased by planting the slipped heads, either in pots or in a shady border, to be afterwards removed into pots for protection in the winter in a frame.

They afford variety in greenhouse collections, among other evergreen potted plants of similar growths.

SIDERNO, in *Geography*, a town of Naples, in Calabria Ultra; 48 miles S. of Catanzaro.

SIDERO-CAPSA, a town of European Turkey, in Macedonia; 32 miles E.S.E. of Saloniki.

SIDEROCHITA, in *Natural History*, a class of crusted ferruginous bodies, of a moderately firm and compact texture, composed of ferruginous mixed with earthy matter, and formed of repeated incrustations, making so many coats or crusts round a softer or harder nucleus, or round loose earths, or an aqueous fluid.

Under this class are comprehended the *emphrepyra*, *heteropyra*, *geodes*, and *enhydri*.

SIDERODENDRUM, in *Botany*, from *σίδηρος*, iron, and *δένδρον*, a tree, a name given by Schreber to the *Sideroxyloides* of Jacquin, which the latter had so called for a while only, till he should be more certain of the genus, by ascertaining the true nature of the fruit. This Schreber has determined; and the name he has chosen alludes to the hardness of the wood, known to the French in Martinico by the appellation of *Bois de fer*, or Iron-wood. The analogy of the neighbouring genus *Sideroxylum* is also thus kept in mind.—Schreb. Gen. 71. Willd. Sp. Pl. v. 1. 612. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 245. (*Sideroxyloides*; Jacq. Amer. 19.)—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Dumofæ*, Linn. *Sapota*, Juss.

Gen. Ch. *Cal.* Perianth superior, of one leaf, minute, with four acute teeth. *Cor.* of one petal; tube cylindrical, incurved, many times longer than the calyx; limb in four oblong, obtuse, flat, reflexed segments, half the length of the tube. *Stam.* Filaments four, very short, inserted under the divisions of the limb; anthers oblong, erect. *Pist.* Germen roundish, inferior; style thread-shaped, the length of the tube of the corolla; stigma oblong, obtuse, thickish. *Peric.* Berry two-lobed, crowned with the calyx, two-celled, with a transverse partition. *Seeds* solitary, convex and rugged at the outer side, flat on the inner, bordered, attached to the partition.

Eff. Ch. Corolla of one petal, salver-shaped. Calyx with four teeth. Berry inferior, two-lobed, two-celled. Seeds solitary.

1. *S. triflorum*. Three-flowered Iron-tree. Willd. n. 1. Ait. n. 1. (*Sideroxyloides ferreum*; Jacq. Amer. 19. t. 175. f. 9. *Sideroxylum americanum*, five lignum duritie ferrum æmulans; Pluk. Almag. 346. Phyt. t. 224 f. 2.)—Native of mountainous woods, in the islands of Martinico, Montserrat, Barbadoes, &c. A tall branching tree. *Leaves* opposite, stalked, ovate-lanceolate, acute, entire, shining, six inches long. *Flower-stalks* axillary, very short, mostly three-flowered, chiefly on the older and leafless branches. *Flowers* small and slender, about half an inch long, rose-coloured at the outside, white within.—Mr. Ryan observed the corolla to be often changed, possibly by the attack of some insect, into an oblong, hollow, fleshy bag, pointed at the top, half an inch in length, resembling a fruit.

SIDEROMANTIA, *Σιδηρομαντία*, in *Antiquity*, a kind of divination performed with a red-hot iron, upon which they laid an odd number of straws, and observed what figures, bendings, sparkings, &c. they made in burning.

SIDEROXYLUM, in *Botany*, from *σίδηρος*, iron, and *ξύλον*, wood, alluding to its hardness, was first correctly applied to the present genus, (as Dillenius observes,) in the *Paradisi Batavi Prodrum*, 375. subjoined to Sherard's *Schola Botanica*; see *SHERARD*.—Linn. Gen. 104. Schreb. 141. Willd. Sp. Pl. v. 1. 1089. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 13. Dill. Elth. 357. Jacq. Amer. 55. Juss. 151. L. marck Illustr. t. 120. Gært. Fil. Suppl. t. 202.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Dumofæ*, Linn. *Sapota*, Juss.

Gen. Ch. *Cal.* Perianth inferior, small, erect, in five segments, permanent. *Cor.* of one petal, wheel-shaped, in five concave, erect, roundish segments, with a little pointed inflexed scale, at the base of each segment. *Stam.* Filaments five, awl-shaped, the length of the corolla, into which they are inserted alternately with the scales; anthers oblong, incumbent. *Pist.* Germen roundish, superior; style awl-shaped, the length of the stamens; stigma simple, obtuse. *Peric.* Drupa roundish, pointed, of one cell. *Seed.* Nut ovate, large, of one cell.

Eff. Ch. Corolla five-cleft. Stamens inserted into the corolla, with five scales between. Stigma simple. Drupa superior.

Obs. SERSALISIA of Mr. BROWN, see that article, differs in having a berry, with from one to five seeds; but in the former case we know not how to distinguish it from the present genus. *Sideroxylum spinosum*, Linn. Sp. Pl. 279, according to Mr. BROWN, constitutes a very distinct genus of the same natural order.

1. *S. mite*. Harmless Iron-wood. Linn. Syst. Nat. ed. 12. v. 2. 178. Willd. n. 1. Jacq. Coll. v. 2. 249. (*S. mas inermis*; Mill. Ic. t. 299.)—Thorns none. Leaves acute.—Native of Africa. Jacquin describes his plant, which appears to be the same with Miller's, as an elegant evergreen tree from the Cape of Good Hope, flowering abroad in summer, sheltered in the greenhouse in winter. The leaves are scattered, stalked, lanceolate, pointed, entire, coriaceous, smooth; of a shining deep green above; paler beneath. *Footstalks* short, purple. *Flowers* white, on simple or branched axillary stalks.—We know nothing of this species but from the above authors. Linnæus defines his plant as having sessile flowers, but we find no specimen in his herbarium to ascertain what he meant.

2. *S. inermis*. Smooth Iron-wood. Linn. Sp. Pl. 278. Willd. n. 2. Ait. n. 1. Jacq. Coll. v. 2. 250. (*Sideroxylii primum*, dein coriæ indorum nomine data arbor; Dill. Elth. 357. t. 265. f. 344.)—Thorns none. Leaves obovate, obtuse. Flower-stalks simple, round.—Native of the Cape of Good Hope. This shrub has long been known in the greenhouses of Europe, but has no beauty to boast, at least in its flowers, which are small and inconspicuous, growing on short, cylindrical, simple, axillary, generally aggregate stalks. The leaves are thick and coriaceous; rounded at the end, and often emarginate; somewhat tapering at the base; two or three inches long.

3. *S. melanophleum*. Laurel-leaved Iron-wood. Linn. Mant. 48. Willd. n. 3. Ait. n. 2. Jacq. Hort. Vind. v. 1. 29. t. 71. (*Padus foliis oblongis, fructu solitario*; Burm. Afr. 238. t. 84. f. 2. *Laurifolia africana*; Commel. Hort. v. 1. 95. t. 100.)—Thorns none. Leaves lanceolate. Flower-stalks simple, angular.—Native of the Cape of Good Hope. Communicated to Linnæus in 1761, by the late professor David Van Royen; and sent to Kew in 1783, by Mr. Græffer. This has dark purplish branches, and elliptic-lanceolate leaves, longer and more acute than the last. The flowers and their stalks are altogether of a palish red hue. Linnæus says the scales between the stamens are wanting, which Jacquin seems to confirm. The fruit is blue, the size of a pea.

4. *S. cymosum*. Cymose Iron-wood. Linn. Suppl. 152. Willd. n. 4. Thunb. Prodr. 36.—Thorns none. Leaves opposite, stalked, ovate. Cymes once or twice compound.—Found by Thunberg on the Table Mountain, at the Cape of Good Hope. A small shrub. We have seen no specimen.

5. *S. sericeum*. Silky Iron-wood. Ait. n. 3. Willd. n. 5. (*Sersalisia sericea*; Brown Prodr. Nov. Holl. v. 1. 530.)—

530.)—Thorns none. Leaves ovate, obtuse; downy, like the calyx and flower-stalks, beneath. Corolla villous externally. Gathered by Mr. Brown, in the tropical part of New Holland; and by Sir Joseph Banks, who sent it to Kew in 1772, in New South Wales. The *style* is slender, hairy at the base.

6. *S. obovatum*. Obovate Iron-wood. (*Serfalifia obovata*; Brown *ibid.* n. 2.)—Leaves obovate; somewhat tapering at the base; scarcely silky beneath. Calyx nearly smooth. Corolla smooth. Style very short.—Gathered by Sir Joseph Banks, in the tropical part of New Holland.—In both these the *scales* between the *stamens* are lanceolate.

7. *S. argenteum*. Silvery Iron-wood. Thunb. Prodr. 36. Willd. n. 6.—“Thorns none. Leaves ovate, abrupt, downy. Flowers stalked.”—Found by Thunberg at the Cape.

8. *S. tomentosum*. Downy Iron-wood. Roxb. Coromand. v. 1. t. 28. Willd. n. 7.—Thorns none. Leaves elliptic-oblong, with a blunt point; downy when young. Flower-stalks downy, axillary, aggregate, the length of the footstalks. Found chiefly on the tops of the mountains in Hindoostan, flowering during the hot season. This is a small tree. The *leaves*, three inches long and one broad, are smooth when full grown, but in a young state are covered with rusty down. *Flowers* numerous, of a dirty white. *Fruit* yellow, the size of a small cherry. Dr. Roxburgh says there are the rudiments of five *seeds*, though only one or two come to perfection. Hence it seems that the generic character, in that respect, is but precarious.

9. *S. lycioides*. Willow-leaved Iron-wood. Linn. Sp. Pl. 279. Willd. n. 8. Ait. n. 4. (*S. spinosum* foliis deciduis; Daham. Arb. v. 2. 260. t. 68. *Bumelia lycioides*; Pursh v. 1. 155.)

β. *S. decandrum*. Linn. Mant. 48. Willd. n. 9. Thorns axillary. Leaves elliptical, deciduous.—Native of North America. In shady woods from Carolina to Georgia, flowering in July and August. A small tree, with minute greenish *flowers*. *Puffs*. The *branches* are round, minutely warty, with strong, spreading, tapering, axillary, solitary thorns, three quarters of an inch long, accompanying the flowers, on the lower part of each branch. *Leaves* alternate, stalked, elliptic-oblong, about three inches in length, and more than one in breadth, entire, somewhat pointed, smooth, light green, finely reticulated with veins, deciduous. *Flower-stalks* axillary, several together, simple, about the length of the spines, and rather longer than the footstalks. *Segments* of the calyx deep, oval, concave, smooth, obtuse, unequal, folding over each other. *Corolla* twice as long as the calyx, but little spreading. We are unable to find any distinction between *S. lycioides* and *decandrum*. A specimen in the Linnæan herbarium from Kalm, under the latter name, has a pentapetalous flower, and is otherwise totally different from the species in question. Our description is taken from the specimen sent by Baron Munchausen to Linnæus, and marked *lycioides* by the latter, though described in his *Mantissa* under the appellation of *decandrum*.

10. *S. spinosum*. Thorny Iron-wood, or Argan. Linn. Sp. Pl. 279, excluding the synonym. Dryand. in Art. Hort. Kew. n. 5. (*Elærodendrum* Argan; Willd. Sp. Pl. v. 1. 1148. *Rhamnus ficulus*; Linn. Syst. Nat. ed. 12. v. 3. 229.)—Thorns lateral. Leaves obovate-oblong, deciduous.—Native of Morocco. This has strong, almost conical, *thorns*. *Leaves* aggregate, stalked, obovate, simple, entire, smooth, about an inch long. *Flowers* in axillary tufts, nearly sessile. *Rhamnus ficulus pentaphyllos*, Boec. Sic. 43. t. 21, must be a very different plant, having really

five leaflets on a common stalk, as Mr. Dryander observes in Tr. of Linn. Soc. v. 2. 225. This learned writer justly remarks, that many East Indian synonyms have erroneously been referred by Linnæus to his *Sideroxylum spinosum*; but he errs respecting the specimen under this name in the Linnæan herbarium, which is evidently the plant belonging to those synonyms, though not to the original specific character, being *Flacourtia sepium*, Willd. Sp. Pl. v. 4. 831. Roxb. Coromand. v. 1. t. 68.

The reader will perceive that there is considerable uncertainty about the species of this genus; nor is there less difficulty respecting its generic character, which is not yet clearly contrasted with that of *BUMELIA*; see that article.

*SIDEROXYLUM*, in *Gardening*, contains plants of the shrubby, evergreen, exotic kinds, of which the species cultivated are; the smooth iron-wood (*S. inerme*); and the willow-leaved iron-wood (*S. lycioides*).

The wood of these shrubby plants having great solidity, hardness, and ponderosity, so as to sink in water, they have obtained the appellation of iron-wood.

*Method of Culture*.—These plants may be increased by seed procured from abroad, which should be sown in the spring in pots filled with fresh mould, and plunged in the tan-bed of the stove: when the plants have some growth, they should be removed into separate pots, and be replunged in the bark-bed. They are also sometimes raised from slit-layers and cuttings in the summer season; but they are tedious in forming roots in this way, and the plants are not so good in general.

The first sort is tender, affording variety in the stove; but the last is more hardy, and may sometimes be introduced in the shrubby borders in warm sheltered situations.

*SIDERS*, in *Geography*, a town of Switzerland, and principal place of a *dixain* in the Valais; 8 miles E. of Sion.

*SIDES-MEN*, properly called *synods-men*, or *quest-men*, persons who, in larger parishes, are appointed to assist the church-wardens in inquiring into the manners of inordinate livers, and in presenting offenders at visitations. In the ancient episcopal synods, the bishop was wont to summon divers creditable persons out of every parish to give information of, and to attest the disorders of clergy and people. These were called “*telles synodales*;” and in after-times they were a kind of impanelled jury, consisting of two, three, or more persons in every parish, who were upon oath to present all heretics and other irregular persons. These, in process of time, became standing officers in several places, especially in great cities, and hence were called “*synods-men*,” and by corruption “*sides-men*.” They are also sometimes called “*quest-men*,” from the nature of their office, in making *inquiry* concerning offences. And these *sides-men* or *quest-men*, by Can. 90, are to be chosen yearly in Easter-week, by the ministers and parishioners (if they can agree); otherwise to be appointed by the ordinary of the diocese. But for the most part this whole office is now devolved upon the *church-wardens*; which see. The *sides-man's* oath, agreed upon by the civilians and common lawyers, is as follows: “You shall swear that you will be assidant to the church-wardens in the execution of their office, so far as by law you are bound: to help you God.” *Gibb. 216.*

*SIDEWAYS*, in the *Manège*. To ride a horse sideways, is to pass him, or make him go upon two treads, one of which is marked by his shoulders, and the other by his haunches.

*SIDGUR*, in *Geography*, a town of Hindoostan, in Baglana; 50 miles E.N.E. of Bilsen.

*SIDI*, in *Hindoo Mythology*, is the name of one of the

two wives of Ganefa or Pollear, the god of prudence and policy. (See POLLEAR.) The name of the other was Budhi, and both were daughters of *Vishwarupa*; which see. Their names occur but seldom in Hindoo writings.

**SIDI Ben Tulu**, in *Geography*, a town of Algiers; 30 miles E.S.E. of Meliana.

**SIDI Eja**, a town of Algiers; 30 miles S. of Boujeiah.

**SIDI Gazi**, a town of Asiatic Turkey, in Natolia; 4 miles N.E. of Kiutaja.

**SIDI Ibrahim**, a town of Algiers; 30 miles W. of Tubnah.

**SIDI Medhab**, a town of Africa, in Tunis; 20 miles N. of Gabs.

**SIDI Shebri**, a town of Asiatic Turkey, in Caramania, on a lake; 6 miles E. of Beisheiri.

**SIDALIEL**, a town of Nubia; 55 miles N. of Sennaar.

**SIDIBISCHIR**, a town of Africa, in the country of Fezzan; 16 miles E. of Mourzouk.

**SIDIN**, or **VATISA**, a river of Asiatic Turkey, which runs into the Black sea, at Vatisa.

**SIDLA**, **SIDLAW**, or *Sudlaw Hills*, a range of mountains in the counties of Perth and Angus, Scotland, which form the southern boundary of the great valley of Strathmore, whence they derive their name; Sudlaws signifying, in Erse, the fourth hills. This ridge commences on the west, in the vicinity of the town of Perth, and extends in a north-eastern direction to Redhead, a promontory on the coast of the German ocean, between Aberbrothwick and Montrose. The mountains which compose it vary considerably in elevation; some of them not exceeding 800 feet in height above the level of the sea, while others are upwards of 1400 feet high. The following are the heights of several of the principal of them, as ascertained by barometrical measurement: Sidlaw hill, 1406 feet; Kingseat, 1238; Kinburnie hill, noted for an ancient tower on its summit, 1151; and Dunfinnan hill, 1024½. The last mentioned hill is remarkable for being that on which the usurper and tyrant, Macbeth, built a castle, with a view to secure his life against any attempt which might be made to murder him. Sinclair's Statistical Account of Scotland, vol. i. 1791.

**SIDMOUTH**, a market-town in the hundred of East Budleigh, and county of Devon, England, is seated in a valley on the banks of the river Sid, between high hills, at the distance of 14½ miles S.E. of Exeter, and 158 miles S.W. of London. Sidmouth was formerly a sea-port of some consequence; but the harbour has been so clogged with sand and pebbles, that pleasure-boats and fishing smacks are the only vessels which can now approach the shore. Of late years the buildings and population have increased, in consequence of the number of persons who frequent the place in the summer, for the purposes of bathing and recreation. Good accommodations have consequently been provided, and a ball-room, billiard-room, and tea-room, erected for the convenience of the visitors. According to the population report in the year 1811, the number of houses in the parish was 349, inhabited by 1688 persons. A weekly market is held on Saturdays, and two fairs annually. Near the beach is an ancient stone building, with very thick walls firmly cemented, traditionally said to have been a chapel of ease, when Otterton was the mother-church; and in a path leading from Sidmouth to Otterton, called Go-Church, is an ancient stone cross. At Sidmouth was formerly an alien priory, a cell to Mountborrow in Normandy, or rather to St. Michael in Per culo Maris; for to this last mentioned monastery the manor was given by king William the Conqueror. It was sometimes reckoned

as a part of Otterton priory, and, with that, after the dissolution of the foreign houses, was given to Sion abbey; and at the time of the surrender, devolved to the crown. The scenery on this coast, between Sidmouth and Seaton, is grand and romantic; presenting a succession of lofty cliffs, sloping ridges, and narrow vallies. In some places the cliffs are composed of sand, tinged by a red oxyd of iron, and is partly calcareous. On the edge of a hill, north-west of Sidmouth, is an ancient encampment, called Woodbury castle, which is of an irregular form, with deep ditches: at some places the foss is double. Observations on the Western Counties, by George Maton, M.D. 2 vols. 8vo. The History of Devonshire, by the Rev. Richard Polwhele, 3 vols. fol. 1797. The Chorographical Description, or Survey of the County of Devon, by Trifram Riddon, 8vo. 1714, 2d edit. 1811. Beauties of England and Wales, vol. iv. 1803, by J. Britton and E. W. Brayley.

**SIDNA-BINES**, a town of Fez, near the sea-coast.

**SIDNEY**, **PHILIP**, in *Biography*. See **SYDNEY**.

**SIDNEY**, **ALGERNON**. See **SYDNEY**.

**SIDNEY**, in *Geography*, a town of the island of Cape Breton; 20 miles N. of Louisburg.—Also, a town of New York, on the Susquehanna; 50 miles W. of Hudson.—Also, a post-town of the province of Maine, on the Kennebeck; 30 miles N.E. of Portland, situated in the county of Kennebeck, and containing 1558 inhabitants.

**SIDNEY Cove**. See **SYDNEY Cove**.

**SIDODONA**, in *Ancient Geography*, a barren place on the coast of Carmania, in the Persian gulf, where Nearchus is said to have refreshed himself, in his voyage from the isle of Oaracta to that of Cara, according to his journal of the navigation.

**SIDOLOUCUM**, or **SIDOLEUCUM**, a town of Gallia Lyonnensis, on the route from Lugdunum to Gessoriacum, between Augustodunum and Abellone, according to the Itinerary of Antonine.

**SIDON**, a town of Phœnicia, 30 miles from Berytus, according to the Itinerary of Antonine. This town was for a long time the metropolis of Phœnicia, till Tyre became more powerful, and contested with it this dignity. Justin says, that the Phœnicians, being obliged to abandon their country on account of an earthquake, established themselves in the vicinity of the lake of Assyria, which they afterwards deserted, and established themselves on the neighbouring coast of the sea, where they built the town, which they called Sidon. Moses informs us that this town had been built by Sidon, the eldest son of Canaan, the father and founder of the Phœnicians. Joshua (ch. ii. v. 8.) says, that the town of Sidon was rich and powerful when the Israelites took possession of the land of Canaan. St. Jerom says, that it fell to the lot of the tribe of Asher. In the year 1015, Sidon was dependent on Tyre, for Solomon induced Hiram, king of Tyre, to give orders to the Sidonians to procure from Libanus the wood which he wanted for the temple at Jerusalem, which he proposed to build. The Sidonians shook off the yoke of the Tyrians 720 years B.C. and surrendered themselves to Salmanazar, when this prince entered into Phœnicia. Josephus (Antiq.) relates, that about 150 years afterwards, Apries, king of Egypt, invaded Phœnicia with powerful armies, took Sidon by force, which event was followed by the submission of all the other towns of Phœnicia to the conqueror. Cyrus conquered this city, but the Sidonians obtained permission of the Persians to have their own kings; and they took part in all the expeditions of their new masters, according to Herodotus (l. iii.); and in the war of Xerxes against the Greeks, the king of Sidon, according to Diodorus Siculus (l. xiv.) commanded

commanded a fleet of forty-eight ships, which very much contributed to the victory which that prince obtained over the Lacedæmonians. The city of Sidon was ruined in the year 351 B.C. under the reign of Ochus, king of Persia. When the inhabitants saw the enemy in the city, they shut themselves up in their houses, with their wives and children, and were there massacred by a conflagration. Diodorus Siculus (l. xvi.) says, that the Sidonians, who were absent during this massacre, and thus escaped destruction, returned thither and rebuilt it, after Ochus had withdrawn to Persia. Arrian (De Exped. Alex.) says, that the Sidonians offered to submit to Alexander, when that prince entered into Phœnicia after the battle of Issus, 333 years B.C. This prince charged Hephæstion to appoint a king for this city; accordingly this officer raised to the throne of Sidon the host with whom he had lodged; but this person declined the charge, and procured the crown for a person of the royal family, called by Diodorus, Ballonymus. After the death of Alexander, Sidon was transferred to the kings of Egypt, and afterwards to those of Syria, until at length it fell under the power of the Romans. This city, according to Strabo, suffered the effects of an earthquake, which demolished half the city. See SAÏDE.

SIDONA. See SIDENA.

SIDONEY, in *Geography*, a town of Hindoostan, in Oude; 42 miles W. of Kairabad.

SIDONIUS, CAIUS, SOLLIS APOLLINARIS, in *Bio-graphy*, was born at Lyons in or about the year 430, of a distinguished family, his father and grand-father having exercised the office of pretorian-prefect in Gaul. He was liberally educated, and obtained great reputation for his literary talents, and especially his skill in the poetical art. Coming to the capital he was raised to the highest offices by several successive emperors. He married Papianilla, daughter of the emperor Avitus, whose accession he celebrated by a long panegyric in verse, which was rewarded by a brass statue of him placed in the portico of Trajan. On the deposition of that prince, he was made a prisoner at Lyons by the emperor Majorian; whose favour he afterwards obtained by a new panegyric. He was now employed by Majorian to negotiate a treaty with Theodoric, king of the Visigoths, of whose person and manners he has left us a curious description. For this service he was rewarded with the title of count. Under Severus Ricimer he defended with the most complete success Auvergne against the incursions of the barbarians. On the accession of Anthemius he was ready with another panegyric, and was in this requited by the government of Rome, and the dignity of patrician was conferred upon him. In the year 472 he renounced all his secular employments, and became a bishop. He is said to have conducted himself with singular piety in his new office, to have been exemplary for charity, and all the episcopal virtues, and to have fed 4000 Burgundians, when under the pressure of famine. He was a great sufferer at the siege of Clermont, and was forced to fly at its surrender, but was very soon restored to his see. He afterwards underwent some trouble from two factious priests, who contended with him the government of the church, and also from some who were deemed by him as heretics; and to this has been ascribed his death, in 487, which has been called a martyrdom. Of the writings of Sidonius, there are extant twenty-four pieces in verse, marked with the debased character of the age, and nine books of Epistles, containing much curious information relative to the learning and history of his times. The best editions of his works are those by Savaron in 1609, and by Sirmond in 1652. Moreri. Gibbon, vol. vi.

VOL. XXXII.

SIDOWLY, in *Geography*, a town of Hindoostan, in Bahar; 10 miles E. of Saferam.

SIDRA, a town of Hindoostan, in Bahar; 18 miles N.W. of Palamow.

SIDRA, *Gulf of*, a large bay of the Mediterranean, on the coast of Tripoli, anciently called "Syrtis," extending from N. lat. 30° 30' to 32° 30', and E. long. 15° 30' to 19° 30'.

SIDRONA, in *Ancient Geography*, a town of Illyria, in the interior of Liburnia. Ptol.

SIDUS, a small borough of the territory of Corinth, E. of Schœnus, which served as a port to Megara. Steph. Byz.—Also, a small borough of Asia Minor, in Ionia, in the vicinity of the town of Clazomene.—Also, another in the vicinity of the Erythraean sea.—Also, a place of Asia Minor, in Pamphylia. Steph. Byz.

SIDUS, *Georgium*, in *Astronomy*. See GEORGIAN Planet.

SIDUSA, in *Ancient Geography*, an island of Asia Minor, upon the coast of Ionia. Pliny.

SIEBELN, or SIEBENLEIN, in *Geography*, a town of Saxony, in the circle of Erzgebirg; 4 miles N. of Freyberg.

SIEBENKEES, JOHN PHILIP, in *Biography*, professor of philosophy and the Oriental languages in the university of Altdorf, and member of the Society of Volsci, at Velletri, was born in 1759 at Nurnberg, where his father was organist to one of the churches. Being intended for the church, he was initiated in the Latin and Greek languages under very able masters, and he applied also with great diligence to the Hebrew and Chaldee. In the year 1778 he repaired to the university of Altdorf, where he attended lectures on the holy scriptures, and where, in conjunction with some of the other students, he established a private literary society, the first-fruit of which was a dissertation on the religion of the ancient Germans, and other Northern people. This piece was published in 1781, and it was so highly esteemed by Ernesti, that he added it to his translation of Tacitus "De Moribus Germanorum," which was printed in 1791. He now became the tutor to some young people, and not only performed the duties attached to the office for six years with high reputation, but was able by diligence and assiduity to apply himself, at the same time, to researches in the literature, history, and arts of the ancients. He collected materials to compose memoirs of the life of Bianca Capello de Medici, grand duchess of Tuscany, which was published in one volume octavo at Gotha, in the year 1789. But the chief part of his attention was directed to the MS. treasures contained in the library of St. Mark, from which so many of the classical authors have been printed and improved. His researches here were much facilitated by Morelli, the librarian, who assisted him greatly in the art of decyphering and reading manuscripts, a business to which he himself had been unaccustomed. Here he examined with great attention the valuable manuscripts of Strabo; and studied with the utmost care the two celebrated manuscripts of the Iliad, of which, before the appearance of Valloison's edition, he gave a circumstantial account in the German work entitled "Bibliothek der Alten Literatur und Kunst." In the same work he published an extract from the Chrestomathia of Proclus; collated some MSS. of Heliodorus; and made selections from the unprinted scholia on Plato and other authors. With the same eagerness he examined and studied the remains of ancient art preserved in different collections at Venice. In 1788 he quitted Venice, and made a tour through many parts of Italy, and at Rome he remained fifteen months, entirely occupied in surveying the works of art, or in studying the manuscripts in different

libraries; and here he was much indebted to Reggio, the learned librarian of the Vatican, who allowed him the use of all those highly valued manuscripts, the greater part of which has been, since that, carried to Paris by the French. From these, Siebenkees made copious extracts for the improvement of Strabo and other ancient authors; and here he transferred the Vatican MS. of the characters of Theophrastus, which is reckoned the completest and most perfect in existence. He collected likewise from this library a large mass of critical matter for the illustration of the classics, in extracts, fragments, and observations. Cardinal Borgia interested himself very much in favour of Siebenkees, and allowed him the free use of his museum at Velletri, where he wrote an explanation of a "Tessera Hospitalis," preserved in it, which was published with the following title: "Expositio Tabulæ Hospitalis ex ære antiquissimo in Museo Borgiano Velitris asservatæ." For this work, which was considered as extremely ingenious, he was elected a member of the learned society of Velletri. On his return to his native country, he visited the most celebrated libraries at Augsburg and Memingen, as well as in various monasteries in Swabia, and formed an acquaintance with many of the German literati. In the year 1790 he returned to Nurnberg, and in the following year he was appointed extraordinary professor of philosophy and of the Oriental languages at Altdorf; after this he was made regular professor of philosophy and history. Between the years 1791 and 1796, besides giving academic lectures on the Oriental as well as the Greek and Latin languages, on mythology, archæology, geography, universal history, the history of literature and of the German empire, he found leisure to publish the following works: "An Essay towards a History of the Inquisition in the Venetian States;" "A Plan for prosecuting the Study of Roman Statistics, for the Use of his Lectures;" "On the Temple and Statues of Jupiter at Olympia," an antiquarian essay. But his most important undertaking was his edition of Strabo, amended and corrected from various readings, and an improved translation, with the following title; "Strabonis Rerum Geographicarum Libri XVII. Græca ad Opt. Codd. MSS. recensuit var. lect. ad notationibusque illustravit Xylandri Verisionem emendavit I. P. Siebenkees." He contributed to many periodical works, such as the "Journal des Luxus," in which he published a picture of Venice; Harles' edition of "Fabricii Bibliotheca Græca," &c. He died in 1796. He was not distinguished by any uncommon strength of genius; but extraordinary diligence, and a most ardent attachment to literary pursuits, enabled him to acquire a very extensive knowledge of languages and literature in general. He was an excellent draughtsman, and this talent was of great assistance to him in his archæological researches in Italy. His writing, in his own language, was exceedingly elegant, but his latinity is neither pure nor correct. His service to literature would have been more important had he lived to finish his Strabo, a great part of the second volume of which was left unprinted at the time of his death. Some other works, on which he had been employed, were also left incomplete, viz. an edition of Theophrastus, from a MS. copy in the Vatican, and his valuable "Anecdota Græca," selected from the best MSS. in the Italian libraries. Both these works were completed after his death, and published at Nurnberg in 1798. Gen. Biog.

SIEBER, in *Geography*, a river of Germany, which runs into the Oder, 5 miles S. of Oiterode.

SIECHAM-HOTUN, a town of Corea, in the sea of Japan. N. lat. 41° 24'. E. long. 127° 24'.

SIEDABAD, a town of Hindoostan, in Benares, on the Ganges; 15 miles N.E. of Benares.

SIEDE, a small river of Germany, which runs into the Wefer, 2 miles S. of Hoya.

SIEDENBERG, a town of Germany, in the county of Hoya; 9 miles S.S.W. of Hoya.

SIEG, a river of Germany, which rises in the east part of Nassau-Siegen, passes by Siegen, Blanckenberg, Siegenberg, &c. and runs into the Rhine, two miles below Bonn.

SIEGBERG, a town of the duchy of Berg; 14 miles S.E. of Cologne. N. lat. 50° 53'. E. long. 7° 18'.

SIEGBERG. See SYBERG.

SIEGE, in *War*, the encampment of an army around a place, with design to take it, either in the way of distress and famine, by making lines all around it, to prevent any relief from without; or by main force, as by digging trenches, and making formal attacks.

The word is French, and signifies, literally, *feat*; alluding to the army's taking its feat before a town, till the reduction of the place.

The most celebrated sieges of antiquity are those of Troy, Tyre, Alexandria, and Numantium; and, among the moderns, those of Ostend, Candia, Grave, Bergen-op-zoom, Gibraltar, &c. See LINE, in *Fortification*.

SIEGE, *To raise a*, is to give over the attack of a place, quit the works thrown up against it, and the posts formed about it.

SIEGE, *To turn a*, into a blockade, see BLOCKADE.

SIEGE-Pieces, in *Coinage*, a division of modern coins, consisting of those that have been issued upon urgent necessity, during a siege, by any city or town. Patin has published a remarkable one of thick paper or parchment, struck at Leyden in 1574, when that place was besieged by the Spaniards. It has a lion rampant, PUGNO PRO PATRIA; and on the reverse this inscription, LUGDUNUM BATAVORUM. Various siege-pieces of gold and silver were issued in the reign of Charles I.; some of the latter being so large as to be of 20s. value.

SIEGEN, in *Geography*, a town of Germany, which gives name to a branch of the house of Nassau, in the vicinity of which are some considerable iron-mines and forges; 37 miles E. of Bonn. N. lat. 50° 48'. E. long. 8° 8'.

SIEGENBURG, a town of Bavaria, on the Ambs; 20 miles E. of Ingolstadt.

SIEGES, LES, a town of France, in the department of the Yonne; 24 miles W.S.W. of Troyes.

SIEGSTADT, a town of Norway, in the province of Aggerhuus; 58 miles N. of Christiana.

SIELE, a town of Lithuania, in the palatinate of Brzesc; 56 miles N.E. of Brzesc.

SIELUB, a town of Lithuania; 8 miles N. of Novogrodek.

SIEMIECZOW, a town of Lithuania; 15 miles W. of Sluck.

SIENAGE, a town of South America, in the province of Tucuman; 130 miles N. of St. Miguel de Tucuman.

SIENE, in *Ancient Geography*, a town of Egypt, situated, according to Pliny, in a peninsula, on the western bank of the Nile, in which was a Roman garrison. See SYENE.

SIENITE, *Granitelle* of Sauffure, in *Geology*, a rock nearly resembling granite, but composed of feldspar and hornblende, and occasionally containing quartz and mica. The name is derived from the city of Sienna, in Upper Egypt, where immense quantities of this stone were worked by the Romans, and large blocks and columns were brought from thence to Rome. The Egyptian sienite is in fact a granite,

granite, intermixed with a small quantity of hornblende. Some sienites are coarsely granular, containing large distinct crystals of red felspar; in other sienites the crystals are very minute, and the hornblende greatly predominates: in the latter case, sienite passes into the rock which the Germans call *grun-stein*, or green-stone. When the sienite is finely granular, but contains large crystals of felspar imbedded, it is then denominated sienite porphyry. This rock frequently occurs in large continuous masses, lying over granite and slate rocks. It is sometimes divided into distinct layers, which, by the German geologists, have been called *strata*; in other instances, it assumes the prismatic or columnar form. Some mineralogists class all those granites with sienite, which contain a portion of hornblende; but this distinction appears useless, for the same mineralogists admit that hornblende is frequently a constituent part of gneiss or slaty granite.

In the infancy of science, substances which are essentially distinct, are apt to be confounded together, if they possess certain points of resemblance; and in a somewhat more advanced state of information, substances, that are essentially the same, are often separated, by artificial classifications, into distinct orders or species, by those who are accustomed to inspect the cabinets of collectors, and overlook the great features of nature. Thus much useless discussion has arisen with respect to certain rocks, whether they were to be classed with granite or sienite, &c. The operations of nature, in the composition of the great rock formations, are not to be limited by the definitions of the mineralogist. Almost all rocks, with the exception of the calcareous, pass by such insensible gradations into each other, that the most experienced eye would find it difficult to class them, from the inspection of detached specimens. Nor will this appear surprising, when we consider that silice generally composes half or more of the substance of all rocks not calcareous, whether simple or compound; and even the distinct concretions in compound rocks generally contain about the same proportion of silice, except quartz, which is almost entirely formed of it. Even in common clay, though the properties of silice are concealed by a portion of alumine, yet it is still the predominating part of the mass. Now whether rocks were consolidated from a solution, or from a state of igneous fusion, the silice, or principal ingredient, as it became variously intermixed with the other earths, would, on consolidation, pass into a vast variety of forms. Where the solution or fusion continued for a longer time undisturbed, the laws of chemical affinity would have freer action, and dispose the different elementary parts to assume those distinct crystalline forms peculiar to certain combinations and proportions of the earths. Where, from change of temperature, or other causes, the play of chemical affinity was interrupted, the mass would become confusedly crystalline, and lose all appearance of crystallization; and between these extremes there might be every possible variety of gradation, such as we now find to exist.

Hornblende appears to be the substance which connects granite with rocks that have a very different external appearance. When hornblende exists in small quantities in granite, it does not change the character of the rock, where the three essential substances, quartz, felspar, and mica, form the prevailing part of the mass; for chlorite, feldspar, and other minerals, are intermixed in small quantities in the granite of the higher Alps. When the quantity of hornblende is increased, and that of the mica and quartz diminished, the rock is properly what mineralogists denominate sienite. When the hornblende and other minerals, except felspar, are so intimately mixed as to form one

homogeneous paste, in which the crystals of felspar are imbedded, it then constitutes a porphyry. When the hornblende greatly predominates, and the felspar is in very small crystals, it forms green-stone. When the crystals are no longer discernible, it forms rocks to which the name of trap have been given. (See TRAP.) Green-stone may be considered as a crystalline variety, and basalt as an earthy variety, of trap. Thus by an intermixture of hornblende, we have an insensible gradation from highly crystalline granite and sienite to a compact earthy rock, in the internal structure of which scarcely any trace of crystallization can be seen.

Sienite is found in Cornwall, and the western side of Wales, and at Chamwood forest in Leicestershire: from the latter place it is sent to London, and to Nottingham and Leicester, cut into blocks for paving-stones. A beautiful green and red sienite forms one of the hills called Markfield, which is described in Mr. Bakewell's Geology, as covered on its summit with pyramidal blocks of the same stone, which he conceives might be employed for durable ornamental architecture. Sienite occurs in many of the mountainous parts of Scotland, but is not, we believe, a metalliferous rock in any part of Great Britain; nor has it, we believe, been applied to any other purpose than for paving-stones. Many of the ancient statues and columns in Egypt are formed of this stone; and it has been before observed, that it was brought in great quantities from that country by the Romans, on account of the vast columns, &c. which could be formed from single blocks. As a proof of its durability, it is stated by travellers that columns which the Romans left unfinished in the quarries of Sienna, nearly two thousand years since, preserve to the present day the impression of the tools as sharp and distinct as if they had been recently worked.

SIEN-KU, in *Geography*, a town of China, of the third rank, in Tehe-kiang; 18 miles W.S.W. of Tai-tehou.

SIENNA, or SIENA, a city of Italy, and capital of a district, in Etruria. This district, called Siennese, or Territorio di Sienna, was once a free republic, conquered by the emperor Charles V. in the year 1554; whose son, Philip II. king of Spain, ceded all parts, except the Stato de gli Præsidi, to Cosmo I. duke of Florence. The city is pleasantly built on three hills, in a healthy situation. The houses are of brick, and the streets paved with the same. It is nearly five miles in circumference, but not peopled in proportion to its size; the inhabitants scarcely exceeding 17,000. It is the see of an archbishop, and the cathedral is a fine Gothic building, coated with white and black marble within and without. The great portal was begun in the year 1284, after the designs of Giovanni da Pisa, and finished in 1333, by Angelino and Agnolo, Siennese architects. The front is prodigiously loaded with ornaments. All the work of the inside is most highly finished, as the carving in wood of the choir; the sculpture in marble of the pulpit; and especially the historical engraving of the pavement, representing in chiaro-scuro the most remarkable stories of the Old and New Testament. From an aperture in the choir pavement may be seen St. John's church, which lies directly underneath. Its entrance is without, on the hill; and thus one church may be said to stand on another. Near the cathedral is the archbishop's palace, and opposite to it a large and well-endowed hospital, founded by a shoe-maker. Here are also many other churches and convents. The church of the Dominicans is remarkable for an ancient picture of wood, representing the Virgin with the infant Jesus in her arms, by Guido Sanece: it is dated 1221, and is in the Venturini chapel: though so ancient,

ancient, it is in good preservation. The university was founded by Charles V. The German students enjoy particular privileges, which they derive from the same emperor. In the 15th century the academy of the Intronati was here founded. This city still retains some shadow of its former republican liberty, which may appear from the manner of electing its council, which consists of nine persons, styled *Excellenzi*; but whose power the great duke very much curtailed. The castle, built at one end of the city, in order to curb the inhabitants, is of no great strength. Near it is the university's academy for martial exercises. Many nobility reside here, who have a casino or assembly of both sexes; and it is generally allowed that the Italian language is in no part of Italy spoken with greater purity; 54 miles S. of Bologna. N. lat. 21°. E. long. 11° 16'.

SIENNE, a river of France, which runs into the sea, near Havre.

SIENNOI, a town of Russia, in the government of Mogilev; 60 miles N.N.W. of Mogilev. N. lat. 54° 30'. E. long. 29° 44'.

SIEN-TCHING, a town of Corea; 23 miles N.W. of Long-kouang.

SIEN-YEOU, a town of China, of the third rank, in Fo-kien; 22 miles N. of Siuen-tcheou.

SIEOU, a city of China, of the second rank, in Kiangnan; 381 miles S. of Peking. N. lat. 33° 45'. E. long. 117° 32'.

SIEOU-GIN, a town of China, of the third rank, in Quang-li; 15 miles N.W. of Yong-ngan.

SIEOU-OU, a town of China, of the third rank, in Ho-nan; 36 miles S.W. of Vue-kian.

SIEOU-YUEN-HOTUN, a town of Chinese Tartary; 330 miles E. of Peking. N. lat. 40° 18'. E. long. 122° 51'.

SIERPERNOI-PESOK, a small sandy island of Russia, in the Frozen ocean. N. lat. 71° 30'. E. long. 106° 14'.

SIER, a river of France, which rises about six miles S.E. of Thonnes, and runs into the Rhône, near Seissel.

SIERAGE, a town of Hindoostan; 32 miles N.W. of Benares.

SIERCK, a town of France, in the department of the Moselle. In 1792, this town was taken by the duke of Brunswick; 9 miles N.N.E. of Thionville.

SIERMAH, a town of Bengal; 24 miles S. of Palamow.

SIERNDORFF, a town of Austria; 7 miles N.W. of Korn-Neuburg.

SIERNING, a town of Austria; 12 miles S.W. of Ebenfurth.

SIERO, a town of Spain, in Asturia; 9 miles N.E. of Oviedo.

SIEROCK, a town of the duchy of Warsaw; 15 miles N. of Warsaw.

SIERRA, the eastern part of New Castile, so called from its mountains. The word Sierra is a general name for mountain in Spain, and those distinctive appellations are often given from the neighbouring towns.

SIERRA *d'Adriana*, mountains of Spain, in Guipuscoa, which took their name from the hermit Adrian. The road leading over it to Alaba and Old Castile is very difficult to travellers. At the very beginning of it is a dark space, between 40 and 50 paces in length, cut through a rock; after which we ascend up a hill, which is reckoned the highest among the Pyrenées. These mountains are but little inhabited, a few shepherds' huts only being to be seen; 18 miles S. of Tolosa.

SIERRA *de Bojar*, a mountain of Spain, in the province of Leon; 20 miles N.N.E. of Plasencia.

SIERRA *Cava*, a small rocky island, near the east coast of Sardinia. N. lat. 39° 46'. E. long. 10°.

SIERRA *del Cid*, a mountain of Spain, in Valencia; 14 miles N.W. of Alicante.

SIERRA *de Cobre*, a mountain of the island of Cuba; 15 miles W. of St. Jago.

SIERRA *de Guadarama*, a mountain of Spain, in the south part of Old Castile; 15 miles S. of Segovia.

SIERRA *di Gador*, a mountain of Spain, in the kingdom of Grenada; composed of marble, of which they make excellent lime; 12 miles S. of Almeria.

SIERRA *de Gredor*, a mountain of Spain, in the province of Leon; 25 miles N.W. of Plasencia.

SIERRA *Jalima*, a mountain of Spain, in Estremadura; 20 miles N.N.W. of Coria.

SIERRA *Leona*, a country of Africa, in Upper Guinea; so called because it is mountainous, and the mountains abound in lions. It is composed of several states or kingdoms, and is well watered by a river of the same name, at the mouth of which an association of English gentlemen established a settlement, on land purchased of the prince of the country. This company was incorporated by act of parliament, in the year 1791. A considerable number of whites and free negroes were conveyed thither from Nova Scotia, besides many who went from England. At first the new settlers seem to have suffered from the want of proper habitations during the rainy season, but subsequent accounts were more favourable. In the month of December 1793, the natives continued perfectly friendly; the neighbouring chiefs shewed every desire of being connected with the company: some had sent their children to be educated at Sierra Leona, and many others proposed to send them in the ensuing dry season. The rainy season had passed over without any considerable mortality; and the Nova Scotia colonists had maintained their health, and appeared to have become well inured to the climate. The trade was much more brisk; the cultivation was advancing, both in the colony and parts adjacent; and there appears to have been no difficulty in procuring the native labourers. The rice, cotton, and other articles in the company's plantation, had thrived exceedingly, the sugar-cane excepted, which had been hurt by the white ants. The school of the company contained between 300 and 400 children, chiefly Nova Scotians, who appear to have made full as much improvement as is common in European schools, under similar circumstances. The colony had gradually improved in order, and appeared to be advancing in every respect; but neither these appearances, nor several parliamentary aids, could support it sufficiently against new difficulties which continually occurred; and the company was dissolved in 1807. Sierra Leona river abounds in fish, but is much infested with alligators. The country adjacent produces abundance of millet and rice; and the woods are filled with parrots of various kinds, and other beautiful birds; serpents are found, some of a very large size; and numerous wild beasts, such as lions, tigers, elephants, wild boars, and monkeys.

The benevolent and laudable exertions of the African Institution, established since the abolition of the slave-trade, have very much contributed to the prosperity of the colony of Sierra Leona. The climate is much better for European constitutions than that of almost any other part of the coast. There are now 400 houses within the walls of Freetown, containing 1917 inhabitants, beside about 2500 Negroes, freed by sentences of the admiralty-court, and residing there under the protection of the government. There is a considerable

siderable number of European forts on the coast, apparently very useless, except for slave-trading purposes. From Apollonia to Acra, a distance of only 64 leagues, there are no fewer than 27; and the expence of the British forts is about 25,000*l.* annually. Government, it is said, has it in contemplation to dismantle all those, except one or two, which will be put in a respectable state of defence. See SLAVE-TRADE.

Amongst the labourers at Sierra Leona there are above 800 persons of the tribe of Kroomen; and they are to be found at every factory and town along the coast, for the space of 350 miles. They are employed as factors or intermediate merchants, boatmen, and sailors; and while the slave-trade was carried on upon this coast, they had their share of its occupation. After the age of 40, they return and settle at home. Their country, or Kroo country, extends along the Grain Coast, between Mount and Cape Palmas, from 4° 54' to 5° 7' N. lat. The chief town, Settra Kroo, is in W. long. 7° 48'. This district, though small, is populous; and the natives are of a migratory disposition. Their country produces grain, particularly fine rice, pepper, and cattle; but their staple article is their own labour, with which they purchase goods, and return to their home with the produce. Wars are rare among these people, and they never sell one another, nor kill their captives; nor do they punish any offence by slavery, though witchcraft is a capital crime, and the only one that is invariably so among them. While the slave-trade lasted, they used to kidnap the "Bushmen," or natives of the interior, and sell them.

These Kroomen are indolent, but when task-work is assigned them, they exert themselves very much; as the reward, in this case, is proportioned to their labour. In their expenditure they are rigid economists, the only luxury which they allow themselves being tobacco. Their whole subsistence is only from 1½ lb. to 1¾ lb. of rice, clean and fit for use, *per* day; and of this they will sell one half, when rice is dear. Though they are fond of rum, they never buy it; and some of them will not drink it, when offered to them. Their clothing does not cost them 10*s.* a year. The residue of their grain they lay out in goods; and in 18 months, or two years, the Krooman returns home with his wealth. This he distributes liberally; and what remains he gives to his father to buy him a wife. Having had a wife, after a few months of ease and indulgence, he sets off again for Sierra Leona. When his coffers are replenished, he returns home, and disposes of his riches as before; reserving a part, which he gives to his father to buy him another wife. Thus he proceeds for twelve years or more, increasing the number of his wives, and establishing a great character among his countrymen.

The Kroomen are peculiarly distinguished by their extreme love of their own country, which they think superior to all others. All their exertions are to obtain a sufficiency, that they may return and live there. They have not the use of letters, and will not permit their children to learn; and as they live by daily labour, which is paid for in European goods, they have no occasion for manufactures of their own. They have few opportunities of displaying peculiar talents; however, they make their own canoes, several of their implements of agriculture, and some trifling musical instruments.

SIERRA Leona, a river of Africa, called also "Ritomba," and "Tagrin," about eight miles broad at its mouth, which runs into the Atlantic ocean, N. lat. 8° 20'. W. long. 12° 30'.

SIERRA *Morena*, a mountain, or rather a chain of mountains, of Spain, between the provinces of Cordova and Jaen to the south, and Estremadura and La Mancha to the north. A few years ago, this district was the dread of travellers. M. le Maur, a Frenchman, who for a long time has been one of the corps of engineers of Spain, was chosen in the year 1779, by the count de Florida Blanca, to render practicable a road the most frequented of any in the kingdom; and he has made it one of the finest in Europe. Several new settlements have been formed, and new towns founded in this barbarous district.

SIERRA *Madre*, a lofty chain of mountains of New Mexico, crossing the province of Cinaloa.

SIERRA *de Motin*, a headland on the coast of Mexico. N. lat. 19° 50'. W. long. 104° 36'.

SIERRA *Nevada*, mountains of Spain; 20 miles E. of Grenada.

SIERRA *Nevada*, or *Iztaccibnath*, a volcanic mountain of Mexico, whose summit is always covered with snow; 30 miles S.E. of Mexico.

SIERRA *de Nostra Senora*, a range of mountains in South America, forming the western boundary of the province of Tucuman.

SIERRA *de St. Mamed*, a mountain of Spain, in Estremadura; 25 miles N. of Badajoz.

SIERRA *de St. Pedro*, a mountain of Spain, in Estremadura; 36 miles S.W. of Truxillo.

SIERRA *de Torquino*, a mountain of the island of Cuba; 25 miles S. of Bayamo.

SIERRA *Vermejo*, a range of hills in Spain, which run westerly towards Malaga, and afford a singular curiosity: for though they run parallel, and so close that their bases join, yet one is red and the other is white; snow will not remain on the highest, whilst it constantly covers the other. The white hills produce the cork-tree, and the Encina oak; the red has no oak, but is covered with firs. The white has iron-ore in little lumps; the red has several ores, but no iron. The waters of the white hills are martial and vitriolic; those of the red sulphureous, alkaline, and with a strong smell like those of Cotterets, in France.

SIEBSBERG, a town of France, in the department of the Moselle, near the river Nied; 4 miles N.N.W. of Sar Louis.

SIEBSHAGEN, a town of the duchy of Holstein; 2 miles N.W. of Neustadt.

SIEBAMO, a town of Spain, in Aragon; 5 miles E. of Huesca.

SIETTREE, a town of Bengal; 4 miles S. of Burwa.

STEEVE, a river of Etruria, which runs into the Arno.

STEEVE, or *Searce*, an instrument serving to separate the fine from the coarse parts of powders, liquors, and the like; or to cleanse pulse from dust, light grains, &c.

It is made of a rim of wood, the circle or space of which is filled with a plexus of silk, tiffany, hair, linen, wire, or even thin slices of wood.

The sieves which have large holes, are sometimes also called *ridles*: such is the coal or lime-sieve, the garden-sieve, &c.

When drugs apt to evaporate are to be passed through the sieve, it is usual to have it covered with a lid.

SIEVERNIVAGOI, or *Ruthen Mountains*, in *Geography*, mountains of Russia, extending between the Baltic and the White sea.

SIEVERNOIPESOK, a small sandy island in the Frozen ocean, near the continent of Russia. N. lat. 76° 54'. E. long. 105° 14'.

SIEVERO-VOSTOCHNOI, a cape on the north coast of

of Russia, called *Cape Taimura* by captain King. N. lat. 78°. E. long. 101° 14'.

SIEVERO-ZAPADNOI, a cape on the north coast of Russia. N. lat. 77°. E. long. 94° 14'.

SIEUGUR, a town of Hindooistan, in Malwa; 9 miles S. of Tandla.

SIEVI, a town of Sweden, in the government of Ulea; 45 miles S. of Brahetlad.

SIEUR, a title of honour, or quality among the French; chiefly used among the lawyers, and in public acts, and other writings of that kind.

The title *sieur* is also given by a superior to an inferior, in his letters and other private writings.

In this sense, authors sometimes use it, by way of modesty, in speaking of themselves: thus, at the heads of books, we see *Traduction du sieur d'Ablancourt*; *Œuvres du sieur d'Espreaux*, &c.

SIEUR is also a term expressing seignery, or lordship: as *ecuyer* or *sieur* of such a place.

SIFACE, GIOVAN FRANCESCO, *Detto*, in *Biography*, a celebrated opera singer in the service of the court of Modena, who obtained the title of Siface from his admirable performance of the part of Syphax, in the old opera of *Mitridate*, modernized by Metastasio, and set by Porpora for Venice in 1730. Algarotti highly praises the pathetic manner in which he sung. Though it is confidently asserted, in the work of a late historian, that Siface had been in England as a singer in the chapel of king James II., yet we can trace no proof of this assertion.

In travelling from Ferrara to Modena, he miserably lost his life in a quarrel with an insolent and brutish postilion.

SI-FANS, or TOU-FANS, in *Geography*, subjects of the Chinese empire, who inhabit to the west of China, and the provinces of Chen-si and Se-tchuen. Their country is only a continued ridge of mountains, inclosed by the rivers Hoang-ho on the N., Ya-long on the W., and Yang-tse-kiang on the E., between the 30th and 35th degrees of north latitude. The Si-fans are divided into two kinds of people; the one are called by the Chinese *black* Si-fans, the other *yellow*, distinctions arising from the different colours of their tents. The black are the most clownish and wretched; they live in small bodies, and are governed by petty chiefs, who all depend upon a greater.

The yellow Si-fans are subject to families, the oldest of which becomes a lama, and assumes the yellow dress. These lama-princes, who command in their respective districts, have the power of trying causes, and punishing criminals; but their government is by no means burdensome: provided certain honours are paid them, and they receive punctually the dues of the god Fo, which amount to very little, they molest none of their subjects. The greater part of the Si-fans live in tents; but some of them have houses built of earth, and even brick. Their habitations are not contiguous; they form at most but small hamlets, consisting of five or six families. They feed a great number of flocks, and are in no want of any of the necessaries of life. The principal article of their trade is rhubarb, which their country produces in great abundance. Their horses are small; but they are well-shaped, lively, and robust.

These people are of a proud and independent spirit, and acknowledge with reluctance the superiority of the Chinese government, to which they had been subjected: when they are summoned by the mandarins, they rarely appear; but the government, for political reasons, winks at this contempt, and endeavours to keep these intractable subjects under by mildness and moderation: it would, besides, be difficult

to employ rigorous means in order to reduce them to perfect obedience—their wild and frightful mountains (the tops of which are always covered with snow, even in the month of July) would afford them places of shelter, from which they could never be driven by force.

The customs of these mountaineers are totally different from those of the Chinese. It is, for example, an act of great politeness among them to present a white handkerchief of taffety or linen, when they accost any person whom they are desirous of honouring. All their religion consists in their adoration of the god Fo, to whom they have a singular attachment: their superstitious veneration extends even to his ministers, on whom they have considered it as their duty to confer supreme power, and the government of the nation.

Some of their rivers wash down gold mixed with their sands: they are acquainted with the art of applying it to use, and form it into vases and small statues, of which they often make offerings to their idol; it even appears that the use of gold is very ancient among them; for Chinese books relate, that under one of the emperors of the dynasty of Han, an officer having been sent to the Si-fans to complain of the ravages committed by some of their chiefs, they endeavoured to appease him by making him a present of a piece of gold plate, which the officer refused, telling the Si-fans, that rice served up in golden dishes was to him insipid food.

These people have lost much of their ancient splendour; for the Si-fans, who at present are confined in a wild country, where they have not a single city, enjoyed formerly an extensive dominion, and formed a powerful and formidable empire, the chiefs of which have often given great uneasiness to the emperors of China. They possessed towards the east several tracts of land, which at present make part of the provinces of Se-tchuen and Chen-si; they even extended their conquests to China, so as to render themselves masters of several cities of the second class, of which they formed four principal governments: in the west, they seized upon all the countries which lie beyond the river Ya-long, and reach as far as the boundaries of Cachemir; but intestine divisions insensibly weakened this great monarchy, and at length brought it to ruin. The Chinese annals fix the epocha of its downfall about the year 1227: since that time, the Si-fans have retired to their native mountains, where, from being a conquering and polished people, they have again sunk into their original barbarity.

SIFEABAD, a town of Hindooistan, in the province of Sirhind; 10 miles S. of Sirhind.

SIFEED RIVER, or *White River*, a river of Persia, so named from the foam occasioned by the rapidity of the current, that flows in a meandering course through Ghilan to the Caspian sea.

SIFFLET, Fr. a cat-call. According to M. Laborde, it was during the reign of Augustus that *clapping* of hands and cat-calls were introduced in the Roman theatres. *Essai sur la Musique*.

SIFTE, in *Geography*, a pretty considerable village of Egypt, between Cairo and Damietta. It has three mosques, and a church belonging to the Copts, the congregation of which consists of 300 families. See SEDFÉ.

SIG, in *Agriculture*, a provincial term applied to urine, or chamber-ley, as employed by the farmer.

SIG, in *Geography*, a lake of Russia, in the government of Olonetz, about forty miles in circumference; 40 miles W. of Povenetz.

SIGA, in *Ancient Geography*, a river of Africa, in Mauritania

ritania Cæsariensis. Ptolemy places the mouth of it between the town of Siga and the mouth of the river Afarath.—Also, a town of Africa, in Mauritania Cæsariensis. It had the title of a colony, and was situated between the port Gypfaria and the mouth of the river Siga. Ptolemy. Strabo says, that this town was destroyed by the Romans, and that the palace of Syphax was here.—Also, a royal town, situated in Africa, in Numidia, and on the western part of the river Mulucha. It was the capital of the kingdom of Syphax.

SIGAGIK, in *Geography*, a town of Asiatic Turkey, in Natolia, on the sea-coast; 14 miles S.W. of Smyrna. N. lat. 38° 18'. E. long. 16° 31'.

SIGAH-*Gush*, or SYAH-*Ghush*, or *Black-Ear*, in *Zoology*, the name of a Persian animal, of the felis or cat-kind, and no way differing from the lynx, but in that it has no spots; it has a lengthened face, and small head; its ears have the fine velvety black pencil of hairs at the top, which are the distinguishing character of the lynx; the inside and bottom of the ears are white; the nose white, the eyes small, the upper part of the body of a very pale reddish-brown, the tail darker, and about half the length of the body; the belly and breast whitish; the limbs strong, and pretty long, the hind-part of each marked with black. This animal inhabits Persia, India, and Barbary; and is used in the chase of lesser quadrupeds, and the larger sort of birds, which they artfully surprize and seize; it is said to attend upon the lion, and to feed on the remains of its prey. It is fierce when provoked. Pennant's *Hist. Quadr.* vol. ii. p. 283. Phil. *Trans.* vol. li. part ii. p. 648, &c.

SIGALA, in *Ancient Geography*, a town of India, on this side of the Ganges, according to Ptolemy, who assigns it to the Mandrales.

SIGANA, a town of Arachosia. Ptolemy.

SIGARAM, in *Geography*, a town of Hindoostan, in Golconda; 12 miles N. of Rachore.

SIGATHA, in *Ancient Geography*, a town of Libya. Strabo.

SIGE, a town of Asia Minor, in the Troade. Steph. Byz.

SIGEAN, in *Geography*, a town of France, in the department of the Aude, near which Charles Martel defeated the Saracens; 9 miles S. of Narbonne.

SIGEBERT I., in *Biography*, king of Austrasia, born about the year 535, was third son of Charles I., king of the Franks. At the death of that sovereign, in 562, his dominions were divided between his sons; and Austrasia, or the kingdom of Metz, fell to the lot of Sigebert. His territories were invaded, soon after his accession, by the Huns, whom he defeated and drove across the Elbe. During his absence, his brother Chilperic made an irruption into Austrasia, and took several places; but Sigebert returning with a victorious army, took Soissons, Chilperic's capital, and defeated Chilperic himself in battle. He was, however, induced to grant him favourable terms, and to restore the conquests made upon him. Sigebert's reputation was now so high, that he obtained for a wife the famous Brunehaut, daughter of the Spanish king of the Visigoths, with a rich portion. The dominions of his brother Caribert, at his death, were shared by the three survivors; but it was not possible for such a divided empire to continue long at peace. Chilperic had married Galswintha, sister of Brunehaut, who was afterwards murdered at the instigation of his mistress, Fredegonde. Brunehaut invited Sigebert, in conjunction with his brother Gontran, king of Burgundy, to revenge this crime, and they over-ran a

great part of his dominions, and forced him to purchase peace by the cession of several places. The Avars, or Huns, soon after made a second irruption into Austrasia, when Sigebert's troops, terrified at their savage appearance, refused to act, and he was obliged to purchase a peace, and supply them with provisions to return to their own country. After this, Sigebert assembling a numerous army, after making himself master of the greatest part of Chilperic's territories, invellid him in Tournay, and refused to listen to terms of accommodation. When the ruin of that prince seemed to be inevitable, Fredegonde, hiring two assassins, who pretending to have some important secret to communicate to Sigebert, thrust their daggers into his body, in the midst of his army. This was in the year 575, after he had reigned 14 years, leaving behind him the character of the greatest and best of the sons of Clotaire.

SIGEBERT, SIGEBERTUS, a monk of Gemblours, in the diocese of Namur, in Brabant, who passed in his time for a man of wit, universal learning, and a good poet. In the younger part of his life he embraced the monastic state in the abbey of Gemblours, under the abbot Olbertus, who died in 1048. During his novitiate he was invited to Metz, where he studied in the school of the monastery of St. Vincent, and acquired great consideration by his learning, in which he was superior to most of the other writers who flourished at the same period. He was acquainted with the Greek and Hebrew languages, and in consequence of the progress he had made in the latter, was much esteemed by the Jews at Metz, where he resided a considerable time, and from which he was with difficulty suffered to depart, in order to return to his former monastery. His celebrity accompanied him thither: he gained many scholars, who did honour to their instructor; and he was chosen by the clergy of Liege to manage their defence in a controversy which they had with the pope, and which he conducted with great talent and moderation. He took sides in the quarrel of Gregory VII., Urban II., and Pascal II., with the emperor Henry IV.; and he wrote against these pontiffs without the least ceremony. Sigebert is author of a Chronicle, the best edition of which was published at Antwerp in 1608, in 4to. It is carelessly written, and in a vulgar style; but contains curious and well authenticated facts. And in endeavouring to ascertain to whom the system of notation by the hexachords belongs, Sigebert in his Chronicle, under the year 1028, as well as in his account of ecclesiastical writers, says, that "he had excelled all his predecessors; as by his method children were taught to sing new melodies, with more facility than by the voice of the master, or the use of an instrument: for by only affixing six letters, or syllables, to six sounds, all that music admits of, regularly, and distinguishing these sounds by the joints of the fingers of the left hand, their distances ascending and descending through the whole diapason, are clearly presented both to the eye and the ear."

Now as Sigebert was nearly contemporary with Guido, his testimony in favour of the discoveries attributed to him have more weight than any proofs that can be adduced from such of his own writings as are generally known. The Chronicle of Sigebert begins at 181, and is continued to 1112; he died the year after.

But what entitles Sigebert to an article in our department, besides his bearing testimony to the inventions of Guido, and his musical records in several other articles of his Chronicle, is the information which he himself gives us in his life, that he had set to music the anthems and responses of St. Guibert; that is, had composed all that was necessary

fary to form an entire office to his honour. And this information is copied by Fabricius, De Script. Ecclef. Arte Musica Antiphonas et refponforia de fanctis.

SIGENBURG, in *Geography*. See SIEGENBURG.

SIGENSUS PORTUS, in *Ancient Geography*, a port of Africa, on the coast of Mauritania Cæfariensis, between Siga and Camarata, according to the Itinerary of Antonine.

SIGER, in *Geography*, a river of Silefia, which runs into the Oder, fix miles below Beuthen.

SIGESBECKIA, in *Botany*, was fo named by Linnæus himself, in memory of his antagonist Dr. John George Siegefbeck, fuperintendant of the phyfic-garden at Petersburgh, who raifed various objections againft the fexes of plants and the Linnæan fyftem, and who has had the honour of being answered by Stillingfleet amongst others.—Linn. Gen. 436. Schreb. 571. Willd. Sp. Pl. v. 3. 2219. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 119. Pursh v. 2. 561. Juff. 187. Lamarck Illuftr. t. 687. Gærtn. t. 168.—Clafs and order, *Synœnefia Polygamia-fuperflua*. Nat. Ord. *Compositæ oppofitifolice*, Linn. *Corymbifera*, Juff.

Gen. Ch. *Outer Common Calyx* of five linear, cylindrical, widely fpreading, permanent leaves, longer than the flower; *inner* fomewhat five-angled, of feveral ovate, concave, obtufe, equal leaves. *Cor.* compound, with a half radius. *Florets* of the difk united, feveral, funnel-shaped, exceeding the calyx in length, with either five or three teeth; of the radius five, or not fo many, all on one fide of the flower, female, ligulate, broad, fhort, three-cleft. *Stam.* in the united florets, Filaments five or three, very fhort; anthers combined in a cylindrical tube. *Pift.* in the united florets, Germen oblong, incurved, the fize of the calyx; fyle thread-shaped, the length of the ftamens; ftigma divided: in the females, Germen oblong, incurved, the fize of the calyx; fyle and ftigma as in the united florets. *Peric.* none, the calyx remaining unchanged. *Seeds* in the united florets folitary, oblong, bluntly quadrangular, thickened upwards, obtufe, naked; down none; in the female ones the fame. *Recept.* chaffy; fcales very like the fcales of the calyx, concave, embracing the feeds at one fide, deciduous.

Eff. Ch. Receptacle chaffy. Seed-down none. *Outer common calyx* of five leaves; *inner* fpreading. Radius all on one fide.

Obf. *S. fofculofa* of L'Heritier offers a fingular exception in this great natural clafs, with regard to number, having the florets of the difk three-cleft, and triandrous.

1. *S. orientalis*. Oriental Sigefbeckia. Linn. Sp. Pl. 1269. Willd. n. 1. Ait. n. 1. (Sigefbeckia; Linn. Hort. Cliff. 412. t. 23. *S. triangularis*; Cavan. Ic. v. 3. 27. t. 253. *Cichoreo affinis*, *Lampfana finica*, *mentaftri folis*, *calyce fimbriato hispido*, *finice hi-him-tfaru dicta*; Pluk. Amalth. 58. t. 380. f. 2.)—Leaves ftalked, ovate, unequally toothed; fomewhat angular at the bafe. *Outer calyx* twice as long as the inner.—Native of China and the Eaft Indies; alfo, according to Cavanilles, of Mexico. Thouin informed the younger Linnæus that he had it from the Cape of Good Hope, and the ftraits of Magellan. The plant has been known for near a century in the gardens of Holland and England, and is a tender annual, flowering in July and Auguft, but with much more fingularity than beauty to recommend it. The *ftem* is bufhy, leafy, round, rough, three or four feet high. *Leaves* oppofite, rough, two or three inches long, fomewhat dilated and triangular at the bafe, tapering down into each footftalk; the uppermoft much fmaller and more oblong. *Flowers* numerous, terminal, ftalked, brownish-yellow, chiefly conspicuous for the fpreading outer leaves of their glandular vifcid *calyx*, each three-

quarters of an inch long. We cannot agree with Willdenow in difcarding Plukenet's fynonym, which furely agrees better with this than with the following.

2. *S. iberica*. Georgian Sigefbeckia. Willd. n. 2. (*Bidentis fimilis*, *foliis latiffimis ferratis*; Buxb. Cent. 3. 29. t. 52.)—Leaves ftalked, ovate, bluntly toothed; rounded at the bafe. *Outer calyx* the length of the inner.—Obferved by Buxbaum about villages in Media, flowering in July. Willdenow, who had feen a dried fpecimen, asserts this to be a very diftinct fpecies from the former, to which Linnæus referred Buxbaum's fynonym. The *leaves*, it feems, are neither triangular, nor cut at the bafe, but fhortly and bluntly toothed. The outer and inner *calyces*, being both of an equal length, feem to us a more certain diftinction.

3. *S. fofculofa*. Small-flowered Sigefbeckia. L'Herit. Stirp. 37. t. 19. Willd. n. 3. Ait. n. 2. Pursh n. 1. Ehrh. Exficc. n. 79.—Leaves nearly feffile, ovate, toothed. Florets of the difk three-cleft, triandrous.—Native of Peru, from whence we believe its feeds were brought or fent by the unfortunate Dombey. This has the habit of the firft fpecies, but the *ftem* is fmooth. The *leaves*, though tapering at their bafe, are fearcely ftalked, nor are they at all dilated, or angular. The greateft peculiarity is found, as we have already faid, in the *flowers*, which are fmaller and paler than thofe of *S. orientalis*, ufually, though we believe not always, deftitute of a radius, but fingularly remarkable for the florets of the difk having only three teeth and three ftamens.

For *S. occidentalis*, Linn. Sp. Pl. 1269, fee PHAETHUSA and VERBESINA.

SIGET, in *Geography*, a town of Hungary, on the frontiers of Poland, near the fource of the Theyffe; 50 miles E. of Munkacz. See alfo ZIGET.

SIGEUM, in *Ancient Geography*, a town and port of Afia Minor, in the Troade, at the diftance of 60 ftadia from the town of Rhæteum, and 100 ftadia from Tenedos. Strabo reports that this town was ruined in his time. The Mylieniens built it; but foon after the Athenians expelled them, which occafioned a long war between thefe two people; but at length, according to Herodotus (l. v.), having fubmitted it to the arbitration of Periander, the fon of Cypfele, this prince adjudged it to the Athenians, in the year 564 B. C. or, according to the computation of Usher, in the year 589. The Athenians kept poffeffion of it till the time of Alexander. Under his fucceffors it was destroyed by neighbouring people. Pliny fpeaks of it as of a town which had long ago fublifted: "quondam Sigæum oppido." Sigæum was re-eftablifhed under the Chriftian emperors, and erected into a bifhopric dependent upon Cyzicus. A miferable village, which has been built upon its ruins, and which prefents a few veftiges of the ancient town, is called by the Turks "Yenitcher-Keui," or village of the janizaries, and "Diagur-Keui," or village of the infidels, as it is no longer occupied except by Greeks. The curious go thither to admire a block of marble, eight or nine feet long, placed by the fide of the door of a church: it bears a Greek infcription, almoft entirely effaced, the words of which follow one another without interruption, *i. e.* that the firft runs, as among us, from left to right, and the fecond runs back from right to left, and fo on to the end. (See BOUSTROPHEDON.) On the other fide of the door is feen a bas relief in marble, tolerably well wrought: it represents a woman feated, to whom other women appear to offer children in fwaddling clothes: behind thefe is feen another woman, holding a box in one hand and a vafe in the other.

**SIGEUM Promontorium**, a promontory of the Troade. It is near to and north of the mouth of the river called Scamander. Strabo calls it the port of the Achæans, because the Greeks landed there in going to the siege of Troy. In the vicinity was a large lake, which was thought to communicate with the sea. This promontory is now called Yeni-Hifari.

**SIGG**, or **SIKKE**, in *Geography*, a river of Algiers, which, united with the Habrah, forms the Muckda, or, as it is first called, Makerra.

**SIGGU**, a town of Japan, in the island of Nippon; 65 miles N.E. of Meaco.

**SIGHING**, an effort of nature, by which the lungs are put into greater motion, and more dilated, so that the blood passes more freely, and in greater quantity, to the left auricle, and thence to the ventricle. Hence we learn, says Dr. Hales, how sighing increases the force of the blood, and consequently proportionably clears and relieves nature, when oppressed by its too slow motion, which is the case of those who are dejected and sad. Hales's *Statistical Ess.* vol. ii. p. 6. See **LUNGS**.

**SIGHT**, the exercise, or act of the sense of seeing. See **EYE**.

Our sight, the noblest and most useful of all our senses, father Malebranche shews, deceives us in abundance of instances; nay, almost in all: particularly with regard to the magnitude and extent of things; their figures, motions, &c. Our eyes do not shew any thing less than a mite: half a mite is nothing, if we believe their report. A mite is only a mathematical point, with regard to it; and we cannot divide it, without annihilating it. In effect, our sight does not represent extension, such as it is in itself; but only the relation and proportion it has to our body. Hence, as half a mite has no relation to our bodies, and that it cannot either preserve or destroy us, our sight hides it entirely. Were our eyes made like microscopes, or were we ourselves as small as mites, we should judge very differently of the magnitude of bodies.

It may be added, that our own eyes are really no other than a kind of natural spectacles; that their humours do the same office as the lens in spectacles; and that, according to the figure of the crystalline, and its distance from the retina, objects are seen very differently by us; inasmuch that we are not sure, that there are any two persons in the world who see them equally big. It is even very rare, that the same person sees the same object equally big with both eyes; as both eyes are very seldom perfectly alike: on the contrary, we generally see things bigger with the left than the right eye; of which we have some very good observations in the journal of the learned at Rome, for the year 1669. See **VISION**.

The *Acta Leipsiensia* give us an account of a man, who received a smart stroke on the pupil of one of his eyes from the end of a fiddle-string, which broke while he was tuning the instrument, and chanced to fly that way. Some cooling things were applied to the eye, and a bandage used to shade it from the light; but at midnight the patient, chancing to wake in the dark, found that he could see with that eye, though not with the other: this continued a long time, and on trial he found that he could read a small print at midnight with this eye, but could scarcely distinguish any thing with it in a bright and clear day.

We have, in the same collections, an account of a man, who, after the cure of a confirmed pox, saw every object double for a long time. *Act. Leips. 1690.*

It is a very common, and a very just observation, that

children do not see any thing clearly when new-born; and if their eyes be then examined, they are found to want that brilliancy which they afterwards acquire; and finally, when any object is presented to their view, they at first turn their eyes about in such a manner, that it is evident they either do not see at all, or at best but very imperfectly and obscurely.

This imperfection may either be owing to a fault in some one of the humours, or in their capsules; or, finally, in the retina, or complexly in them all together. It is impossible to discover whether there be any imperfection in the retina in this state of life, that membrane being ever, in new-born infants, tender and soft like a jelly: if it be in any of the other parts that the imperfection lies, it must be either in their nature or extent. M. Petit, of the Academy of Sciences at Paris, determining to enquire thoroughly into the cause of this, was at the pains of dissecting the eyes of several infants which had died soon after their birth, and in three-fourths of them he found the vitreous, the crystalline, and the capsule, all greatly deficient in their transparency. The uvea appeared also more opaque than in adults, and the pupil over-large; and that there was either none, or, at the utmost, very little of the aqueous humour; and in those eyes where the humours had not this opacity, they were all, as were also the membranes, of a reddish colour; and this was observed in fœtuses of seven and nine months old.

The cornea in these eyes was also remarkably thick, which is, in general, found to be the case in the eyes of all fœtuses. The thickness and opacity in these corneæ gradually diminish in time, and that soon; so that the eyes of children appear much brighter at two or three months old than when new-born. The aqueous humour seems also, in most fœtuses, to be wholly wanting; and where it is found, is ever greatly in an under proportion to the other humours.

It therefore appears, that the dimness and imperfection of sight, in new-born infants, are owing to the over-thickness of the cornea, and to the too small portion of the aqueous or watery humour. It appears plainly also, from experience, that the eye is not able, in infants, to bear the light, till the pupil is greatly contracted; as is the case also, though in a less degree, in adults; and it is very probable, that the extreme softness of the retina in this state may make every ray of light affect it much more plainly than when grown more firm.

M. Petit having continued his examinations of the eyes of infants, up to the age of five or six weeks, found in all his dissections, that the cornea daily grew more and more convex and glossy; and this may be rationally concluded to be owing to the daily increase of the aqueous humour, which must, by that accretion, throw it out into a greater convexity, and make it daily more and more thin and transparent. The uvea also acquires a greater extension, and its fibres become more moveable; whence the pupil acquires a power of enlarging or contracting itself, at the approach or absence of light, with much more ease and readiness than it could before. The humours thus all become capable of letting in a larger quantity of light; the retina is at the same time every day gaining a new firmness, and the pupil becomes capable of an easy dilatation, or restriction, for the letting in occasionally a greater or less number of rays, and the refractions are perfected by the augmentation of the aqueous humour. It is plain, therefore, that the clearness of vision must every day increase. All this change comes on in infants only by time; and it may be judged of, as to its state, by inspection, by the brilliancy and convexity of the cornea, and by the manner of their turning their eyes towards objects set before them; and this time is not cer-

tain, or limited, but differs greatly in different children, some being able to see clearly at the end of a month, others not till after many months.

At the time that this gentleman was dissecting the eyes of human fœtuses and infants, he also curiously observed the eyes of young quadrupeds. The puppy, when newly brought forth, has always its eyes opaque; the kitten, on the contrary, has them clear, and every way like those of adults of the same species. In fœtuses of other quadrupeds, the lamb has its cornea a little turbid and opaque; the calf and the pig have them more or less opaque, but the calf so most of all. Mem. de l'Acad. Par. 1727.

**SIGHT, Point of.** See POINT of View.

**SIGHT, Line of.** See COLLIMATION.

**SIGHT.** Singing or playing at sight, in Music, is the being prepared by long practice and experience for every difficulty, not only of execution, but style and expression: as a person allowed to read well in a book which he has never seen, must not only pronounce the words correctly and distinctly, but observe the punctuation, and enter into the author's design. We do not always give credit to reports of diletants, or even every professor, performing à vista, or, as the French call it, *à livre ouvert*, all kinds of composition without study or practice. See GRETRY.

**SIGHTS, in Mathematics,** denote two thin pieces of brass, raised perpendicularly on the two extremes of an alidade or index of a theodolite, circumferentor, or other like instrument; each of which has an aperture or slit up the middle, through which the visual rays pass to the eye, and distant objects are seen. Their use is, for the just direction of the index to the line of the object.

Sometimes the slits or apertures have glasses or lenses fitted into them; in which case, they are called *telescopic sights*, by way of distinction from the former; which, in respect of the others, are denominated *plain sights*.

Mr. Flamsteed and Dr. Hooke absolutely exploded the use of plain sights in astronomical observations. The errors in Tycho's latitudes of the stars Mr. Flamsteed ascribes wholly to his using plain sights; and suspects, that Hevelius, using the same kind of sights, must fall into the like errors. Hevelius, on the contrary, in a paper in the Philosophical Transactions, vindicates the use of plain sights, and prefers them to telescopic ones: the main objection he makes to the latter is, that no observation can be safely taken with them, without first examining and rectifying them; in which examination, many and gross mistakes are likely to be committed. To which he adds, that in sextants, octants, azimuth quadrants, &c. he does not see how such examination can be made, at all times, without much loss of time.

**SIGILLARIA,** a solemn feast held among the ancient Romans; thus called from a custom which obtained therein, of sending little presents from one to another, consisting of seals, little figures, and sculptures, made of gold, silver, brass, or even earthenware, and of devoting them to Saturn, as an atonement for themselves and their friends.

The Sigillaria followed immediately after the Saturnalia, and held two days; which, with the five days of the Saturnalia, made a solemnity of seven days.

Some derive the origin of sigils and figures, in this solemnity, from the argei, or rushen figures of men, thrown an-

nually into the Tiber, from the Pons Sublicius, by the Vestals, on the ides of March. Vide Macrob. Saturn. lib. i. cap. 7. 10. and 11. See also ARGEA.

**SIGILLATA TERRA,** a name given to several kinds of medicinal earths marked with seals, to express their being genuine. The principal is the Lemnian earth: this is a kind of earth, or bole, dug in the isle of Lemnos, and then also called Lemnian earth; of considerable use in medicine.

It was anciently found in a mountain, in the neighbourhood of the city Hephæstia, where Diana's priests went, at certain times, with great ceremony, to dig it up. After a little preparation, they made it up into troches, and sealed them with Diana's seal; whence the appellation of *sigillata, sealed*.

**SIGILLO,** in Geography, a town of Italy, in Umbria; 12 miles N. of Nocera.

**SIGILLUM,** a seal, or signet.

**SIGILLUM Marie, Lady's Seal,** in Botany, a name by which some authors have called the *bryonia nigra*, or black bryony, a climbing plant, common in hedges.

**SIGILMESSA,** in Geography. See SUGULMESSA.

**SIGINDUNUM,** in Ancient Geography, a town of Upper Mœsia, on the banks of the Danube, according to Ptolemy. The Itinerary of Antonine marks it on the route from Rimini to Byzantium, between Taurunum and the mount of Gold.

**SIGINNI,** a people of Asia, who, according to Strabo, had the same manners with the Persians.

**SIGISA,** a town of Hispania, upon the Tader, N.W. of Vergilia.

**SIGISMONDO,** in Biography. See INDIA.

**SIGISMUND,** emperor of Germany, and king of Hungary and Bohemia, was the son of the emperor Charles IV. of the house of Luxemburg. He was born in the year 1366, and at an early age was sent to the court of Lewis, king of Hungary, to one of whose daughters he was betrothed, with the intention of making him successor to the throne. During his minority, a party of nobles conferred the crown on Charles, king of Naples, on which event Sigismund retired to Bohemia. Charles being assassinated by the contrivance of the queen-mother, who was put to death for the crime, Sigismund assembled an army, and entering Hungary, liberated his wife Mary, who had been imprisoned, and was crowned king when he was in the twentieth year of his age. He severely revenged the execution of his mother-in-law; and getting possession of the persons of the nobles who had invited Charles, he caused them all to be beheaded, to the number of thirty-two. The bloody act occasioned so much disaffection, that the Turkish emperor Bajazet determined upon taking the opportunity of invading Hungary, which he did with complete success; and Sigismund was dethroned. He however escaped, and retiring to Bohemia, levied troops, with which he recovered his crown, and being brought to reason by adversity, he thenceforth conducted himself so as to obtain the goodwill of his people; and such was the reputation which he now acquired abroad, that he was elected emperor of Germany.

The first object of Sigismund in his new dignity, was to put an end to various disorders and dissensions which prevailed in Germany. He held a conference with pope John XXIII. for the convoking of a council, the principal object of which was the termination of the schism in the papacy which had long divided the church. He engaged with great zeal in this matter, and at length effected the assembling of a council at Constance, in 1414, at which he himself assisted. As the opposition of the Hussites to the doctrines

of Rome was now making great progress, the emperor granted a safe-conduct to John Huss to come to the council, and defend the articles of his faith; and it will be to his everlasting disgrace, that he suffered the council to violate the protection he had solemnly given, and to bring this reformer to the stake. He now endeavoured to re-establish peace among the Christian princes, that they might concur in a plan for restoring the unity of the church: with this view he visited both France and England, then at war with each other, but with little success. The council, however, agreed in deposing the existing popes, and electing a new one. Upon the death of his brother Wenceslaus, in 1419, Sigismund succeeded to the crown of Bohemia, which country was in a flame, from the revolt of the persecuted Hussites, under their leader the famous Ziska. He marched with an army into Bohemia, but was entirely defeated by Ziska, and the same fortune attended him a second time. After the death of that hero, a long series of bloody wars succeeded, which at last terminated in the submission of the *Thaborites*, as the insurgents were afterwards called, and Sigismund was crowned at Prague, in the year 1436, and reduced the whole kingdom to obedience. He had some years before this received the imperial crown both at Milan and at Rome. His bigotry urged him to tyrannical proceedings against his Bohemian subjects, which excited their animosity to such a degree, that he determined to leave the country. When he was just upon the point of putting this resolution into execution, he was seized with a mortification in his toes, which was the presage to approaching dissolution, and having publicly declared his son-in-law, Albert, duke of Austria, the heir to his dominions, he died in December 1437, in the 71st year of his age, and the 27th of his imperial dignity. Sigismund is said to have had a fine person, and to have possessed various accomplishments, especially an uncommon skill in the learned languages. He was, moreover, a patron of learned men, was liberal, brave, and active; but, on the other hand, he was cruel, vindictive, and superstitiously devoted to the clergy. He was licentious in his conduct, the consciousness of which made him indulgent to the open and abandoned debauchery of his second wife, Barbara de Cilly, denominated the *Messalina of Germany*.

SIGISMUND I. king of Poland, surnamed the *Great*, was the son of Casimir IV. He succeeded his brother Alexander in 1507, and immediately applied himself to the remedying of abuses that had crept into the administration of public affairs. In this arduous task he was assisted by the able and faithful minister John Bonner, whose name is still held in veneration by the Poles. A rebellion in Lithuania, abetted by the czar of Muscovy, joined to an incursion of the Walachians and Moldavians, obliged him to put himself at the head of the troops, and he completely succeeded against his enemies. The next antagonist with whom he had to contend, was the marquis of Brandenburg, grand-matter of the Teutonic order, who had refused to acknowledge the sovereignty of the king of Poland over the province of Prussia: in this dispute he was also successful, and obliged the marquis to grant him half the province of Prussia, as a barrier against the Teutonic knights. Sigismund now sat down the peaceful sovereign of Poland, Lithuania, the duchies of Smolensko and Severia, and considerable territories on the Euxine and Baltic, while his nephew Lewis was king of Hungary and Bohemia. This accumulation of power gave umbrage to the house of Austria; which, by its intrigues, incited the Walachians, Tartars, and Muscovites, to make new incursions. These, however, were soon driven back with great loss to their own countries, and Sigismund left again in peace. He died, after a wife, fortunate, and

long reign, in the eighty-fourth year of his reign, and in the year 1548.

SIGISMUND II. named Augustus, king of Poland, son of the preceding, was elected to the crown before his father's death. He offended the nobles by marrying the widow of an obscure person; and it is asserted, that, in order to recover their favour, he permitted them to send their sons for education to the Protestant universities of Germany, which was the means of introducing their opinions into Poland. He himself remained attached to the old religion, and by his prudent and moderate conduct kept out of the kingdom those disorders which disturbed the peace of so many other European countries. He was extremely diligent in promoting the improvement of his states by wise laws and regulations, and the correction of abuses, which enabled him to maintain a powerful standing army without the addition of new taxes. This force he had occasion to employ as an auxiliary to his kinsman the archbishop of Riga, against an invasion of the Russians. He made himself master of great part of Livonia, and forced the grand-master of the Teutonic order, who had called in the Russians, to renounce their alliance, and put the order under the protection of Poland. From this period Livonia was annexed to Poland, and the grand-master abdicating his dignity, received in compensation the duchies of Courland and Semigallia, which long remained in his family. The czar, John Basilowitz, made an irruption into Lithuania, which occasioned much bloodshed and devastation, and Sigismund was glad to propose an armistice; and while this measure was in discussion, the king of Poland died in 1572, leaving only two daughters, and with him terminated the male line of the house of Jagellon. He left a high character for courage, ability, and every princely quality, but he is said to have been too much attached to the fair sex.

SIGISMUND III. king of Poland, surnamed *De Vasa*, was the son of John III. king of Sweden, and Catharine, daughter of Sigismund I. king of Poland. He was born in 1566, and in 1587 was elected to the crown of Poland, in competition with Maximilian of Austria. Through the exertions of Zamoski, the crown-general, after a civil war, in which Maximilian was defeated and taken prisoner, Sigismund was firmly seated on the throne. He governed successfully with the assistance of Zamoski, till the death of his father, in 1592, left him heir to the crown of Sweden. As he was a zealous Catholic, and the Swedes were friendly to the Reformation, they felt disinclined to come under his authority; besides that, the duties of a king of Sweden, and of a king of Poland, seemed to be quite incompatible. His uncle, duke Charles, who had been declared regent during Sigismund's absence, inflamed those discontents. Sigismund having obtained permission from the Polish diet to visit his other kingdom, arrived in Sweden in 1593, accompanied by the pope's nuncio, and his proceedings soon proved how much the restoration of the Catholic religion was the object of his wishes. Violent dissensions arose between him and the states, and in 1595 he returned to Poland, leaving Sweden in the greatest disorder. In 1598, Sigismund again entered Sweden at the head of a foreign army, and a civil war ensued, which terminated in a pacification, and the king returned to Poland. Peace did not last long, and in 1604 the Swedes formally deposed him, and raised his uncle Charles to the throne. War succeeded between Poland and Sweden, which ended in the conquest of Livonia by the Polish general.

Russia, at this time, being thrown into confusion by a revolution, Sigismund took part in its disorders, and entering that country, in 1610, at the head of a numerous army,

gained in the outlet such advantages, that he was enabled to place his son Uladiflaus on the throne. He was, however, soon after dethroned, and all the conquests made by Sigismund were recovered by the Russians. During the remainder of his reign, the Poles were involved in wars with the Turks, and afterwards with the Swedes under Gultavus Adolphus. To the latter they were obliged to cede Livonia, Finland, and Prussia; and the concluding years of Sigismund were clouded with disasters. He fell into a state of melancholy and disease, by which he was carried off, in the year 1669. His character has been thus drawn in very few words: "With some talents for government, his religious bigotry, and obstinacy of temper, precipitated him into errors which cost him one crown, and rendered the other a source of perpetual disquiet."

SIGIUS, in *Ancient Geography*, a town of Italy, on the coast of Aufonia, according to Appian.

SIGIUS *Mons*, or *Setius*, according to Ptolemy, a mountain of Galha Narbonnensis, on the coast of the Mediterranean sea. Strabo.

SIGMA, among the *Romans*, the same with the *stibadium*.

SIGMARINGEN, in *Geography*, a town and county of Germany, invested in the house of Hohenzollern, on the Danube; 44 miles E. of Stuttgart. N. lat. 48° 2'. E. long. 9° 16'.

SIGMOID, in *Anatomy*, an epithet applied to various parts of the body, from their figure being similar to that of the Greek letter  $\sigma$ . Thus, we have the sigmoid cavities of the ulna (see *EXTREMITIES*); sigmoid flexure of the colon (see *INTESTINE*); and sigmoid valves of the aorta and pulmonary artery. See *HEART*.

SIGN, SIGNUM, a sensible mark, or character, denoting something absent or invisible.

Anciently the monks, in all religious houses, were not allowed to speak, nor to express their minds, otherwise than by signs, which they learned in their noviciate. C. Rhodiginus and Porta have written of the ancient signs and cyphers used in speaking and writing.

SIGN, in *Algebra*, denotes a symbol, or character.

SIGNS, *like*, *negative*, and *radical*. See the adjectives.

SIGN, in *Medicine*, any appearance in a disease which is cognizable by the senses, and from which some judgment may be formed respecting the nature of the disease, and its probable termination. It is now more commonly called a *symptom*; which see.

SIGN, *Antecedent*. See *ANTECEDENT*.

SIGN, in *Astronomy*, a twelfth part of the ecliptic, or zodiac; or a portion, containing thirty degrees of it.

The zodiac was divided, by the ancients, into twelve segments, called signs; commencing from the point of intersection of the ecliptic and equinoctial; which signs they denominated from the twelve constellations, which, in Hipparchus's time, possessed those segments. But the constellations have since so changed their places, by the precession of the equinox, that Aries is now got out of the sign called Aries, into Taurus, Taurus into Gemini, &c.

The names of the twelve signs, and their order, are as follow: *Aries, Taurus, Gemini, Cancer, Leo, Virgo, Libra, Scorpio, Sagittarius, Capricornus, Aquarius, Pisces*; each of which, with the stars thereof, see under its proper article, *ARIES, TAURUS, &c.*

The signs are distinguished, with regard to the season of the year when the sun is in them, into *vernal, aestival, autumnal*, and *brumal*.

SIGNS, *the vernal, or spring*, are, Aries, Taurus, Gemini.

SIGNS, *the aestival, or summer*, are, Cancer, Leo, and Virgo.

SIGNS, *the autumnal*, are, Libra, Scorpio, and Sagittarius.

SIGNS, *the brumal, or winter*, are, Capricornus, Aquarius, and Pisces.

The vernal and summer signs are also called *northern* signs.

And the autumnal and brumal signs, *southern* signs.

SIGNS, *Ascending*. See *ASCENDING*.

SIGNS, *Fixed*. See *FIXED*.

SIGNS, *Masculine*. See *MASCULINE*.

SIGN *Manual*, the setting one's hand and seal to a writing. See *SIGNATURE*.

The expression is used when any bill or writing is signed under the hand of the king, &c. Counterfeiting the sign manual, privy signet, or privy seal, is treason. 1 Mar. stat. 2. cap. 6. See *PATENTS*.

Among the Saxons, before the invention of seals, a + was a common sign, or *signum*, prefixed to the names of most subscribing witnesses in charters, and other deeds: as + *signum Roberti Episcop. Lond. &c.* See *SEAL*.

SIGN of *Reference*, in *Music*, *signa repetitionis*. See *SEGNO*.

SIGNS of *Disease in Horses*, the appearances which shew them to be out of order. The first sign of a horse's indisposition is, his loathing his food, especially when he has a wild and haggard look; as the eye of a horse is, as it were, a glass, through which may be discerned the inward disposition of his body: it should also be observed whether his ears be cold, his mouth hot or clammy, the hair of his flanks rough and staring, and paler than usual about the ends; his dung hard, black, or greenish, and his urine clear like water. In this case his eyes are also subject to weep; his head is heavy and hanging down; he is apt to stumble as he walks; he is slow and dull, though he was vigorous before; he never minds other horses; contrary to his former custom, he rises and lies down often in the stable, looking towards his flanks, which are doubled and folded in; his heart beats quick; and he is also indifferent and unconcerned at what is done to him. These and many other signs are met with in horses which are not in a state of perfect health, and should be immediately attended to; and suitable remedies be applied. This is of much consequence to be taken care of in team and other work horses belonging to farms, &c.

SIGNA, STANDARDS, among the Romans, were of different sorts; on some of them the image of the emperor was represented, and they that carried them were called *imaginiferi*; others had a hand stretched out, as a symbol of concord; and these ensign-bearers were called *signiferi*; some had a silver eagle, the bearers of which were called *aquiliferi*; others had a dragon with a silver head, and the rest of his body of taffety, which was blown by the wind as if it had been a real dragon, and the bearers of this ensign were called *draconarii*; lastly, the emperor's ensign was called *labarum*, and those that carried it *labariferi*, which they carried out when he went in person to the field; it was of a purple colour, beset with gold fringe, and adorned with precious stones.

All these ensigns were sustained with a half-pike, sharp at the end, that it might be the more easily fixed in the ground.

SIGNAL, a certain sign agreed upon for the conveying of intelligence to places to which the voice cannot reach.

Signals are given for the beginning of a battle, or an attack; usually with drums and trumpets: at sea, they are given by cannon or musket-shot, by lights, sails, flags, &c.

All signals may be reduced into three different kinds; *viz.* those which are made by the sound of particular instruments, as the trumpet, horn, or sife; to which may be added, striking

## SIGNALS.

striking the bell, or beating the drum; those which are made by displaying pendants, ensigns, and flags, of different colours; or by lowering or altering the position of the sails; and those which are executed by rockets of different kinds; by firing cannon or small arms; by artificial fire-works; and by lanthorns. See TELEGRAPH.

The signals by the drum, made use of in military exercise, instead of the word of command, are as follow: a short roll, *q. d.* to caution; a flam, to perform any distinct operation; to arms, to form the line or battalion; the march, to advance, except when intended for a salute; the quick march, to advance quick; the point of war, to march and charge; the retreat, to retreat; drum ceasing, to halt; two short rolls, to perform the flank-firing; the dragon march, to open the battalion; the grenadier march, to form the column; the troop, to double divisions; the long roll, to form the square; the grenadier march, to reduce the square to the column; the preparative, to make ready and fire; the general, to cease firing; two long rolls, to bring or lodge the colours.

Signals have been in use in all ages: the ancients, who had no regular couriers, or posts, made use of them to convey intelligence of what passed at a great distance; for which purpose, they placed sentinels on the eminences, from space to space; some mention of which we find made by Homer himself, *Iliad*  $\odot$ . v. 553, &c. *Odyss.*  $\Xi$ . v. 261. Those people, thus disposed, lighted fires, or flambeaux, in the night-time. In the Agamemnon of Æschylus, that prince, at his departure for Troy, promises Clytemnestra, that, the very day the city should be taken, he would apprize her of his victory by fires, lighted express. He keeps his word, and tidings are brought the princess, that Troy is taken, and that Agamemnon's signals are seen.

Frontinus observes they were in use among the Arabs; and Bonaventura Vulcanius, in his scholia on Aristotle's book *De Mundo*, adds, that, while the Moors were masters of the greatest part of Spain, they built on the tops of the mountains an infinity of turrets, or watch-houses, called, in the Arabic, *atalayas*, a word the Spaniards still retain; whence, by fires, they could immediately alarm the whole kingdom. Indeed the custom was much more ancient than the Moors in Spain. Q. Curtius observes, it was very frequent among the Asiatics, in the time of Alexander: Livy and Cæsar, also, both mention it as used among the Romans. Polydore Virgil shews it of great antiquity in England; and Boethius adds, that, in several places in England, there were the remains of huge poles that have served for this purpose.

**SIGNALS at Sea**, are signs made by the admiral, or commander-in-chief of a squadron of ships, either in the day, or by night, whether for sailing, for fighting, or for the better security of the merchant-ships under their convoy. See ENGAGEMENT.

These signals are very numerous, and important; being all appointed and determined by order of the lord high admiral, and lords of the admiralty, and communicated in the instructions sent to the commander of every ship of the fleet, or squadron, before their putting out to sea. It is by the combination of signals, previously known, that the admiral conveys orders to his fleet; every squadron, every division, and every ship of which has its particular signal. The instruction may, therefore, occasionally be given to the whole fleet, or to any of its squadrons, to any division of those squadrons, or to any ship of those divisions. Hence the signal of command may at the same time be displayed for three divisions, and for three ships of each division; or for three ships in each squadron, and for only nine ships in the whole

fleet. For, the general signal of the fleet being shewn, if a particular pendant be also thrown out from some remarkable place on the same mast with the general signal, it will communicate intelligence to nine ships that wear the same pendant.

The preparatory signal given by the admiral to the whole, or any part of his fleet, is immediately answered by those to whom it is directed; by shewing the same signal, to testify that they are ready to execute his orders. Having observed their answers, he will shew the signal which is to direct their operations: as, to chase, to form the line, to begin the engagement, to board, to double upon the enemy, to rally or return to action, to discontinue the fight, to retreat and save themselves. The dexterity of working the ships in a fleet depends on the precise moment of executing these orders, and on the general harmony of their movements; a circumstance which evinces the utility of a signal of preparation.

As the extent of the line of battle, and the fire and smoke of the action, or other circumstances in navigation, will often prevent the admiral's signals from being seen throughout the fleet, they are always repeated by the officers next in command; by ships appointed to repeat signals; and, finally, by the ship or ships for which they are intended. The ships that repeat the signal, besides the chiefs of squadrons or divisions, are usually frigates lying to windward or leeward of the line. These should be extremely vigilant to observe and repeat the signals, whether they are to transmit the orders of the commanders-in-chief, or his seconds, to any part of the fleet; or to report the fortunate or distressful situation of any part thereof. By this means, all the ships from the van to the rear will, unless disabled, be ready at a moment's warning to put the admiral's design in execution. To preserve order in the repetition of signals, and to favour their communication, without embarrassment, from the commander-in-chief to the ship for which they are designed, the commanders of the squadrons repeat after the admiral; the chiefs of the divisions, according to their order in the line, after the commanders of the squadrons; and the particular ships, after the chiefs of the divisions; and those, in return, after the particular ships, *vice versa*, when the object is to convey any intelligence from the latter to the admiral. Besides the signals above-mentioned, there are others for different ranks of officers; as for captains, lieutenants, masters, &c. or for any of those officers of a peculiar ship. Falconer.

Signal-flags are hoisted at the mizen-peek, &c.; night-signals are made with lanthorns, and are hoisted by the same haliards as the flags. Since November 1805, the red flag at the main-mast has been the first in rank after the union flag. See FLAG.

**SIGNALS by Day.** When the commander-in-chief would have them prepare for sailing, he first looses his fore-top-sail, and then the whole fleet is to do the same. When he would have them unmoor, he looses his main-top-sail, and fires a gun, which, in the royal navy, is to be answered by every flag-ship. When he would have them weigh, he looses his fore-top-sail, and fires a gun, and sometimes hauls home his sheets; the gun is to be answered by every flag-ship, and every ship is to get to sail as soon as it can. If with the leeward-side, the sternmost ship is to weigh first. When he would have the weather-moat and head-moat ships to tack first, he hoists the union-flag at the fore-top-mast-head, and fires a gun, which each flag-ship answers; but if he would have the stern-moat and leeward moat ships to tack first, he hoists the union-flag at the mizen top-mast-head, and fires a gun; and when he would have all the whole fleet tack, he hoists an union both on the fore and mizen-top-mast-heads, and fires a gun. When, in bad weather, he

would

## SIGNALS.

would have them wear, and bring to the other tack, he hoists a pendant on the ensign-staff, and fires a gun; and then the leeward-most and stern-most ships are to wear first, and bring on the other tack, and lie by, or go on with an easy sail, till he comes a-head: every flag is to answer with the same signal. If they are lying by, or falling by a wind, and the admiral would have them bear up and sail before the wind, he hoists his ensign, and fires a gun, which the flags are to answer; and then the leeward-most ships are to bear up first, and to give room for the weather-most to wear, and sail before the wind, with an easy sail, till the admiral comes a-head. But if it should happen, when the admiral hath occasion to wear and sail before the wind, that both jack and ensign be abroad, he will haul down the jack, before he fires the gun to wear, and keep it down till the fleet is before the wind. When they are falling before the wind, and he would have them bring-to, with the starboard tacks aboard, he hoists a red flag at the flag-staff, on the mizen-topmast-head, and fires a gun. But if they are to bring-to, with the larboard tack, he hoists a blue flag at the same place, and fires a gun, and every ship is to answer the gun. When any ship discovers land, he is to hoist his jack and ensign, and keep it abroad, till the admiral or commander-in-chief answer him, by hoisting his; on sight of which, he is to haul down his ensign. If any discovers danger, he is to tack and bear up from it, and to hang his jack abroad from the main-topmast cross-trees, and to fire two guns; but if he should strike or flick fast, then, besides the same signal with his jack, he is to keep firing, till he sees all the fleet observe him, and endeavour to avoid the danger. When any sees a ship or ships more than the fleet, he is to put abroad his ensign, and there keep it, till the admiral's is out, and then to lower it, as often as he sees ships, and stand in with them, that so the admiral may know which way they are, and how many; but if he be at such a distance, that the ensign cannot well be discovered, he is then to lay his head toward the ship or ships so deferred, and to brail up his low sails, and continue hoisting and lowering his top-sails, and making a waft with his top-gallant sails, till he is perceived by the admiral. When the admiral would have the vice-admiral, or him that commands in the second post of the fleet, to send out ships to chase, he hoists a flag, striped white and red on the flag-staff, at the fore-topmast-head, and fires a gun. But if he would have the rear-admiral do so, he then hoists the same signal on the flag-staff at the mizen-topmast-head, and fires a gun. When the admiral would have any ship to chase to windward, he makes a signal for speaking with the captain, and he hoists a red flag in the mizen shrouds, and fires a gun; but if to chase to leeward, a blue flag; and the same signal is made by the flag, in whose division that ship is. When he would have them give over chase, he hoists a white flag on his flag-staff at the fore-topmast-head, and fires a gun; which signal is to be made also by that flag-ship which is nearest the ship that gives chase, till the chasing ship sees the signal. In case of springing a leak, or any other disaster, that disables their ship from keeping company, they are to haul up their courses, and fire two guns. When any ship would speak with the admiral, he must spread an English ensign, from the head of his main or fore-topmast, downwards on the shrouds, lowering his main or fore-top-sail, and continue firing guns, till the admiral observe him; and if any ship perceive this, and judgeth the admiral doth not, that ship must make the same signal, and make the best of his way to acquaint the admiral therewith, who shall answer by firing one gun. When the admiral would have the fleet to prepare to anchor, he hoists an ensign, striped red, blue, and

white, on the ensign-staff, and fires a gun; and every flag-ship makes the same signal. If he would have the fleet moor, he hoists his mizen-top-sail, with the clew-lines hauled up, and fires a gun. If he would have the fleet cut or slip, he looses both his top-sails, and fires two guns; and then the leeward ships are to cut or slip first, to give room to the weather-most to come to sail. So if he would have any particular ship to cut or slip, and to chase to windward, he makes the signal for speaking with that ship, hoists a red flag in the mizen-shrouds, and fires a gun; but if a ship is to chase to leeward, he hoists a blue flag as before. If he would have the fleet exercise their small arms, he hoists a red flag on the ensign-staff, and fires a gun; but if the great guns, then he puts up the pendant over the red flag.

*SIGNALS by Night*, to be observed at an anchor, weighing anchor, and sailing, are as follow. When the admiral would have the fleet to unmoor, and ride short, he hangs out three lights, over one another in the main-topmast-shrouds, over the constant light in the main-top, and fires two guns, which are to be answered by the flag-ships; and each private ship hangs out a light in the mizen-shrouds. Note, that all guns, fired for signals in the night, must be fired on the same side, that they may make no alteration in the sound. When he would have them weigh, he hangs a light in the main-topmast-shrouds, and fires a gun, which is to be answered by all the flags; and every private ship must hang out a light in his mizen-shroud. When he would have them tack, he hoists two flags on the ensign-staff, over one another, above the constant light in his poop, and fires a gun, which is to be answered by all the flags; and every private ship is to hang out a light extraordinary, which is not to be taken in, till the admiral takes in his. After the signal is made, the leeward-most and stern-most ships must tack as fast as they can; and the stern-most flag-ship, after he is about on the other tack, is to lead the fleet, and him they are to follow, to avoid running through one another in the dark. When he is upon a wind, and would have the fleet veer, and bring-to on the other tack, he hoists up one light at the mizen-peek, and fires three guns; which is to be answered by all the flag-ships; and every private ship must answer, with one light at the mizen-peek. The stern-most and leeward-most ships are to bear up so soon as the signal is made. When he would have them, in blowing weather, to lie a-try, short, or a-hull, or with the head-sails braced to the mast, he will form lights of equal height, and fire five guns, which are to be answered by the flag-ships, and then every private ship must shew four lights; and after this, if he would have them to make sail, he then fires ten guns, which are to be answered by all the flags, and then the head-most and weather-most ships are to make sail first. When the fleet is falling large, or before the wind, and the admiral would have them bring-to, and lie by, with their starboard tacks aboard, he puts out four lights in the fore-shrouds, and fires six guns; but if with the larboard tacks aboard, he fires eight guns, which are to be answered by the flag-ships; and every private ship must shew four lights. The wind-most ships must bring-to first. Whenever the admiral alters his course, he fires one gun, without altering his lights, which is to be answered by all the flag-ships. If any ship hath occasion to lie short, or by, after the fleet hath made sail, he is to fire one gun, and shew three lights in his mizen-shrouds. When any one first discovers land, or danger, he is to shew as many lights as he can, to fire one gun, and to tack, or bear away from it; and if any one happen to spring a leak, or any be disabled from keeping company with the fleet, he hangs out two lights of equal height, and fires guns till he is relieved

## SIGNALS.

by some ship of the fleet. If any one discovers a fleet, he is to fire guns, make false fires, put one light out on the main-top, three on the poop, to steer after them, and to continue firing of guns, unless the admiral call him off, by steering another course, and fire two or three guns, for then he must follow the admiral. When the admiral anchors, he fires two guns, a small space of time one from the other, which are to be answered by the flag-ships, and every private ship must shew two lights. When the admiral would have the fleet to moor, he puts a light on each top-mast-head, and fires a gun, which is to be answered by the flag-ships, and every private ship is to shew one light. If he would have them lower their yards and topmasts, he hoists one light upon his ensign-staff, and fires one gun, which is to be answered by the flag-ships; and every private ship must shew one light. And when he would have them hoist their yards and topmasts, he puts out two lights, one under the other, in the mizen-topmast-shrouds, and fires one gun, which is to be answered by the flag-ships; and each private ship must shew one light in the mizen-shrouds. If any strange ship be discovered coming into the fleet, the next ship is to endeavour to speak with her, and bring her to an anchor, and not suffer her to pass through the fleet. And if any one discovers a fleet, and it blows so hard that he cannot come to give the admiral timely notice, he is to hang out a great number of lights, and to continue firing gun after gun, till the admiral answers him with one. When the admiral would have the fleet to cut or slip, he hangs out four lights, one at each main-yard-arm, and at each fore-yard-arm, and fires two guns, which are to be answered by the flag-ships; and every private ship is to shew one light.

*SIGNALS used when a Ship fails in a Fog.* If the admiral would have them weigh, he fires ten guns; which every flag-ship is to answer. To make them tack, he fires four guns, which are to be answered by the flag-ships; and then the leeward-most and stern-most ships must tack first, and after they are about, to go with the same fail they tacked with, and not to lie by, expecting the admiral to come a-head; and this is to avoid the danger of running through one another in thick weather.

When the admiral brings-to, and lies with his head-fails to the mast; if with the starboard tack aboard, he fires six guns; but if with the larboard tack, he fires eight guns, which the flag-ships are to answer. And after this, if he makes fail, he fires ten guns, which the flag-ships must answer, and then the head-most and weather-most ships are to make fail first. If it grow thick and foggy weather, the admiral will continue failing, with the same fail set that he had before it grew foggy, and will fire a gun every hour, which the flag-ships must answer; and the private ships must answer, by firing of muskets, beating of drums, and ringing of bells. But if he be forced to make either more or less fail than he had, when the fog began, he will fire a gun every half-hour, that the fleet may discern whether they come up with the admiral, or fall altern of him; and the flags and private ships are to answer, as before. If any one discovers danger, which he can avoid, by tacking and standing from it, he is to make the signal for tacking in a fog; but if he should chance to strike, and stick fast, he is to fire gun after gun, till he thinks the rest have avoided the danger. When the admiral would have the fleet to anchor, he fires two guns, which the flags are to answer; and after he hath been half an hour at an anchor, he will fire two guns more, to be answered by the flags as before, that all the fleet may know it.

*SIGNALS for calling Officers on board the Admiral.* When the admiral puts abroad an union-flag in the mizen-shrouds,

and fires a gun, all the captains are to come aboard him; and if, with the same signal, there be also a waft made with the ensign, then the lieutenant of each ship is to come on board. If an ensign be put abroad in the same place, all the masters of the ships of war are to come on board the admiral. If a standard on the flag-staff be hoisted at the mizen-topmast-head, and a gun fired, then all the flag-officers are to come aboard the admiral. If the English flags only, then a standard in the mizen-shrouds, and fire a gun; if the flags, and land general officers, then the admiral puts abroad a standard at mizen-topmast-head, and a pendant at mizen-peek, and fires a gun. If a red flag be hoisted in the mizen-shrouds, and a gun fired, then the captains of his own squadron are to come aboard the admiral; and if, with the same signal, there be also a waft with the ensign, the lieutenant of each ship must come aboard. If he hoists a white flag, as before, then the vice-admiral, or he that commands in the second post, and all the captains of his squadron, are to go on board the admiral; if a blue flag, &c. then the rear-admiral, and the captains of his squadron, must come aboard, and if with a waft, as before, the lieutenants. When a standard is hoisted on the ensign-staff, and a gun fired, the vice and rear-admirals must come on board the admiral's ship. When the admiral would speak with the captains of his own division, he will hoist a pendant on the mizen-peek, and fire a gun; and if with the lieutenants, a waft is made with the ensign, and the same signal; for whenever he would speak with the lieutenants of any particular ship, he makes the signal for the captain, and a waft also with the ensign. When the admiral would have all the tenders in the fleet come under his stern, and speak with him, he hoists a flag, yellow and white, at the mizen-peek, and fires a gun. But if he would speak with any particular ship's tender, he makes a signal for speaking with the captain she tends upon, and a waft with the jack. If all the pinnaces and barges are to come on board, manned and armed, the signal is a pendant on the flag-staff, hoisted on the fore-topmast-head, and a gun fired; and if he would have them chase any ship, vessel, or boat in view, he hoists the pendant, and fires two guns. The signal for the long-boats to come on board him, manned and armed, is the pendant hoisted on the flag-staff, and the mizen-topmast-heads, and a gun fired; and if he would have them chase any ship, vessel, or boat, in open view, without coming on board him, he hoists the pendant, as aforesaid, and fires two guns. When the admiral would have all the boats in the fleet to come on board him, manned and armed, he hoists a pendant on the flag-staff, both on the fore-topmast and mizen-topmast-head, and fires one gun; but if he would have them chase, he hoists his pendants, as before, and fires two guns. When the admiral would speak with the victualler, or his agent, he puts an English ensign in the mizen-topmast-shrouds; and when with him that hath the charge of the gunner's stores, he will spread an ensign at his main-topmast-yard-arm.

*SIGNALS for managing a Sea-fight.* When the admiral would have the fleet form a line of battle, one ship a-head of another, he hoists an union flag on the mizen-peek, and fires a gun; and every flag-ship does the like. But when they are to form a line of battle, one a-breast of another, he hoists a pendant with the union-flag, &c. When he would have the admiral of the white, or him that commands in the second post, to tack, and endeavour to gain the wind of the enemy, he spreads a white flag under the flag at the main-topmast-head, and fires a gun; and when he would have the vice-admiral of the blue do so, he doth the same with the blue flag. If he would have the rear-admiral of

the red do so, he spreads a red flag from the cap, on the fore-topmast-head, downward on the back-stay; if the vice-admiral of the blue, he spreads a blue flag, &c. and fires a gun. If he would have the rear-admiral of the red do so, he hoists a red flag at the flag-staff, at the mizen-topmast-head; if the rear-admiral of the white, a white flag; if the rear-admiral of the blue, a blue flag, and under it a pendant of the same colour, with a gun. If he be to leeward of the fleet, or any part of it, and he would have them bear down into his wake or grain, he hoists a blue flag at the mizen-peek, and fires a gun. If he would be to leeward of the enemy, and his fleet or any part of it be to leeward of him, in order to bring these ships into the line, he bears down with a blue flag at the mizen-peek, under the union-flag, (which is the signal for battle,) and fires a gun; and then those ships that are to leeward of him, must endeavour to get into his wake or grain, according to their station in the line of battle. When the fleet is sailing before the wind, and he would have him, who commands in the second post, and the ship of the starboard quarter, to clap by the wind, and come to the starboard tack, he hoists a red flag at the mizen-topmast-head; but a blue one, if he would have ships of the larboard quarter come to the larboard tack, with a gun. If the van are to tack first, he spreads the union-flag at the flag-staff, on the fore-topmast-head, and fires a gun, if the red flag be not on board; but if it be, then he lowers the fore-topmasts a little, and the union-flag is spread from the cap of the fore-topmast downward; and every flag-ship doth the same. If the rear be to tack first, he hoists the union-flag on the flag-staff, at the mizen-topmast-head, and fires a gun; which all the flag-ships are to answer. If all the flag-ships are to come into his wake or grain, he hoists a red flag at his mizen-peek, and fires a gun; and all the flag-ships must do the same. If he would have him that commands in the second post of his squadron to make more sail, (though he himself shorten sail,) he hoists a white flag on the ensign-staff. But if he that commands in the third post be to do so, he hoists a blue flag, and fires a gun, and all the flag-ships must make the same signal. Whenever he hoists a red flag on the flag-staff at the fore-topmast-head, and fires a gun, every ship in the fleet must use their utmost endeavour to engage the enemy, in the order prescribed them. When he hoists a white flag at his mizen-peek, and fires a gun, then all the small frigates of his squadron, that are not of the line of battle, are to come under the stern. If the fleet be sailing by a wind in the line of battle, and the admiral would have them brace their head-sails to the mast, he hoists up a yellow flag, on the flag-staff, at the mizen-topmast-head, and fires a gun; which the flag-ships are to answer, and then the ships in the rear must brace first. After this, if he would have them fall their head-sails, and stand on, he hoists a yellow flag on the flag-staff of the fore-topmast-head, and fires a gun, which the flag-ships must answer; and then the ships in the van must fall first, and stand on. If, when this signal is made, the red flag at the fore-topmast-head be abroad, he spreads the yellow flag under the red. If the fleets being near one another, the admiral would have all the ships to tack together, the sooner to lie in a posture to engage the enemy, he hoists an union-flag on the flag-staves at the fore and mizen-topmast-heads, and fires a gun; and all the flag-ships are to do the same. The fleet being in a line of battle, if he would have the ship that leads the van hoist, lower, set, or haul up any of her sails, he spreads a yellow flag, under that at his main-topmast-head, and fires a gun, which signal the flag-ships are to answer; and the admiral will hoist, lower, set, or haul up the sail, which he would have the ship that leads the van

do; which is to be answered by the flag-ships of the fleet. When the enemies run, and he would have the whole fleet follow them, he makes all the sail he can after them himself, takes down the signal for the line of battle, and fires two guns out of his fore-chase, which the flag-ships answer; and then every ship is to endeavour to come up with and board the enemy. When he would have the chase given over, he hoists a white flag at the fore-topmast-head, and fires a gun. If he would have the red squadron draw into a line of battle, one abreast of another, he puts abroad a flag, striped red and white, on the flag-staff at the main-topmast-head, with a pendant under it, and fires a gun; if the white or second squadron is to do so, the flag is striped red, white, and blue; if the blue or third squadron is to do so, the flag is a Genoese ensign and pendant; but if they are to draw into a line of battle, one a-head of another, the same signals are made with a pendant. If they are to draw into the line of battle one a-stern of another, with a large wind, and he would have the leaders go with the starboard tacks, aboard by the wind, he hoists a red and white flag at the mizen-peek, and fires a gun; but if they should go with the larboard tacks aboard, by the wind, he hoists a Genoese flag at the same place; which signals, like others, must be answered by the flag-ships.

**SIGNATORES**, among the Romans, witnesses who sealed wills and marriage contracts.

**SIGNATURE**, **SIGNATURA**, *Signing*, a subscription, or putting of one's name at the bottom of an act, or deed, in one's own hand-writing.

Anciently, when very few people could write, they dispensed with the use of signatures; and contented themselves with the party's seal. See **DEED**.

**SIGNATURE of the Court of Rome**, is a supplication answered by the pope, by which he grants a favour, dispensation, or collation to a benefice, by putting the *fiat* at the bottom of it, in his own hand; or the *concessum est* written in his presence. This signature, at the bottom of the supplication, gives name to the whole instrument.

The signature contains the clauses, derogations, and dispensations, with which the pope grants the favour, or the benefice, with a commission for the execution of it, either in *forma dignum*, or in *gracious form*.

A signature of the pope's own hand, by which he answers, *Fiat ut petitur*, is preferred to another answered by the *profect*, in his presence, in these words, *Concessum uti petitur in presentia D. N. pape*. Sometimes in signatures, with the *fiat*, the pope adds, *proprio motu*; which clause gives them still farther force.

There are three kinds of signatures: one in *forma gratiosa*, dispatched on an attestation of the ordinary; another in *forma dignum antiqua*, dispatched for canonicates; the third in *forma dignum novissima*, which is a kind of second signature, or executorial letter, granted where, upon the ordinary's failing to execute the first, within thirty days, the nearest other ordinary is enjoined to execute it.

**SIGNATURE**, in *Printing*, denotes a mark at the bottom of each sheet, to regulate the gathering and binding of the book; and to shew the order and number of the sheets, in collating, to see if the book is perfect.

The signatures consist of the capital letters of the alphabet. If there be more sheets than letters in the alphabet, to the capital letter they add a small one of the same sort; *i. e.* a little a after a great A, &c. which they repeat as often as is necessary.

**SIGNATURE**, *Signatura*, is also used, by some naturalists, for the resemblance a vegetable or mineral bears to any part of the human body; this is, by some fantastical people,

people, supposed to afford an indication of its virtues and use.

**SIGNAU**, in *Geography*, a town of Switzerland, and principal place of a district, in the canton of Berne; 12 miles S.E. of Berne.

**SIGNES**, a town of France, in the department of the Var; 12 miles S.W. of Brignoles.

**SIGNET**, one of the king's seals, used for sealing his private letters, and signing all grants which pass his majesty's hand by bill. Forging it is treason. See **SIGX Manual**.

The signet is always in the custody of the king's secretaries; on whom attend four clerks of the signet-office. See **SECRETARY** and **CLERK**.

**SIGNIA**, in *Ancient Geography*, a town of Italy, in Latium, at some distance to the right of the Latin way, and towards the S.W. of Anagnia. Livy says, that Tarquin the Proud sent thither a colony. Some remains of it are still visible.—Also, a mountain of Asia Minor, in the Greater Phrygia. Pliny says, that the town of Apamæa was built at the foot of this mountain.

**SIGNIFER**, among the Romans, an ensign-bearer, or the person who carries the standard, on which was represented a hand stretched out. See **SIGNA**.

**SIGNIFICATION**, the sense or meaning of a sign, word, phrase, emblem, device, or the like; that is, the thing denoted by such sign, word, figure, &c.

We are almost perfectly at a loss as to the signification of the hieroglyphic characters of the ancients.

**SIGNIFICATION**, in *Law*, is the notification of an act, &c. made to the opposite party, by a copy, &c. of it, given and attested by a proper officer.

Some significations are to be made to the person himself; or at least at his house: for others, it is enough that they be made to the party's attorney, or agent.

**SIGNIFICAVIT**. See **EXCOMMUNICATO Capiendo**.

**SIGNING**. See **SIGNATURE**, and **COUNTER-signing**.

**SIGNINUM**, among the Romans, a kind of pavement much esteemed: it was made of powdered shells mixed with lime.

**SIGNORELLI, LUCA**, in *Biography*, was born at Cortona in 1439, and was a disciple of Pietro della Francesca. He was among the first of the Italian artists who designed the naked figure with fidelity and accuracy; though still impeded by the shackles of stiffness and formality, and too much adherence to common nature. His greatest work is his celebrated fresco in the chapel of the Virgin in the cathedral at Orvieto, representing the final dissolution and judgment of the world; a work of extraordinary quality, in which variety and originality of ideas are rendered with force and effect. Vasari, who was related to Signorelli, says that Michael Angelo adopted, in his Last Judgment, many of the ideas of this artist; of which most probably he only took the characters of actions, and clothed them with his own emphatic style of design.

Though grace of form, and harmony of colouring, are not the most prominent features in the style of Signorelli, yet one of his works is extolled by Lanzi as possessing these qualities in a superior degree; viz. his Communion of the Apostles, in the church del Gesu at Cortona. He was invited to Rome to assist in decorating the apartments of the Sistine, where he painted the Journey of Moses and Zipporah, and the Promulgation of the old Law; exhibiting a superior arrangement of composition. He painted at Urbino, Volterra, Arezzo, Siena, and Florence, and established a name among the most eminent of the Florentine painters. He died in 1521, aged 82.

Vol. XXXII.

**SIGNORELLI, PIETRO NAPOLI**, of Naples, author of an excellent critical history of the stage, "*Storia Critica de' Teatri*," 1783. This work is written with great spirit, and, in general, exactitude and genuine information, concerning other theatres, as well as those of Italy; particularly of Spain, where the author had resided twenty years, and with whose literature and dramatic productions he seems perfectly well acquainted. But having given the preference to the dramatic works and performance of the Italians, he provoked a controversy with a Spanish writer, which was not carried on with great patience or urbanity.

Signor Signorelli is likewise author of a work more voluminous and important, entitled "*Vicende della Coltura nelle due Sicilie*;" or, "*Progress in the Culture of Legislation, Policy, Literature, Commerce, Fine Arts, and Theatrical Exhibitions, in the Two Sicilies*," 5 vols. 8vo. Naples, 1786. This work contains much information of the progress of music at Naples during the two last centuries; but we were disappointed in finding no mention of the Conservatorios, those famous musical seminaries which have produced so many great composers and fingers, whose works and performance have not only delighted Naples and the rest of Italy, but all Europe.

**SIGNORESSA**, in *Geography*, a town of Italy, in the Trevisan; 6 miles N.W. of Treviso.

**SIGNUM PUCNÆ**, the signal of battle among the Romans, was a coat of arms of a purple colour, set upon the general's pavilion.

**SIGNY-le-Grand**, in *Geography*, a town of France, in the department of the Ardennes, and chief place of a canton, in the district of Mezieres; 6 miles S.W. of Charleville. The place contains 2380, and the canton 6699 inhabitants, on a territory of 210 kilometres, in 13 communes.

**SIGNY-le-Petit**, a town of France, in the department of the Ardennes, and chief place of a canton, in the district of Rocroy; 9 miles W.S.W. of Rocroy. The place contains 1723, and the canton 5790 inhabitants, on a territory of 142½ kilometres, in 10 communes.

**SIGONIO, CARLO**, in *Biography*, was born of a good family at Modena, about the year 1524. At the age of seventeen he went to Bologna, where he passed three years in the study of philosophy and medicine, to which last profession he was destined by his father. But having no turn for physic, he spent a year at Pavia, and then entered into the service of cardinal Grimani. At the age of twenty-two he was taken by invitation from his native city to occupy the chair of Greek, vacant by the departure of Porta, the master under whom he had formerly studied. In 1550 he made himself advantageously known to the learned world by publishing the "*Falci Consulares*," with a commentary, which quickly went through several editions. In 1552 he was invited to the professorship of belles-lettres at Venice, and in that city he published seven discourses on important topics of literature, and his valuable notes and conjectural emendations of Livy. In 1560 he was removed to the chair of eloquence at Padua, then the most celebrated of the Italian universities, but in 1563 he accepted an invitation to Bologna, which was from this time the usual place of his residence. In this situation he rendered himself to acceptable to the city, that he was presented with its freedom, together with a large increase of salary. Here he employed himself in the composition of learned works, which have handed down his name to posterity with high honour, and he was so well satisfied with his condition, that he refused a very flattering proposal from Stephen, king of Poland, to occupy a professorship in that country.

country. He visited Rome in 1578, where he was honourably received by pope Gregory XIII., by whom he was engaged to compose an ecclesiastical history. Of this, however, he executed no more than some learned illustrations of Sulpicius Severus; for he died at Modena in the year 1584. He was a most able and successful elucidator of ancient history and antiquities. He was indefatigable in searching to the bottom all subjects which he undertook to examine, so that in many he left little to be added by later enquirers, and his works are all carefully composed in a pure, and even an elegant, Latin style. Besides the pieces already mentioned, he published many valuable tracts on the Roman laws and customs, also on the republics of the Hebrews, Athenians, and Lacedæmonians. He composed twenty books of a history relating to the western empire, from the time of Dioclesian to its final destruction, and he performed the more arduous task of framing from the rude and obscure chronicles of the times, a history of the kingdom of Italy, from the arrival of the Lombards to the year 1286. Sigonio was involved in several controversies, in one of which he is supposed to have disgraced himself. About twelve months before he died, an intimate friend of his edited a pretended treatise of Cicero, entitled "Consolatio." Its authenticity was immediately impugned by critics, and there is now no doubt that it was not genuine; but Sigonio wrote so warmly in defence of it, that he is generally supposed to be the author. The works of this learned man were published collectively in 1732-3, by Argelati, at Milan, in six vols. fol. with his Life, by Muratori, prefixed.

**SIGORUM**, in *Ancient Geography*, a mountain of Asia, in Mesopotamia, in the vicinity of the town of Niſbis, according to Sozomen.

**SIGOULES, LE**, in *Geography*, a town of France, in the department of the Dordogne; 7 miles S. of Bergerac.

**SIGRI**, a town on the N.W. part of the island of Metelin, in the Grecian Archipelago.

**SIGRIANA**, in *Ancient Geography*, a country of Asia, in Media, according to Strabo.

**SIGRIANI**, mountains of Asia Minor, on the coast of the Propontide.

**SIGRIUM**, a promontory of the isle of Lesbos, in the most westerly part of the island.

**SIGRUM**, a port of the isle of Tenedos, in which was a statue of Diana.

**SIGTUNA**, in *Geography*, a town of Sweden, in the province of Upland, situated on a creek of the Malar lake, anciently one of the chief cities of the kingdom. It is said to derive its name from the celebrated Odin, whose surname was Sigge: he came into the north before the Christian era, and had his residence, his temple, and his court of justice; others say the town was built by Odin. However that be, Sigtuna has undergone many changes; in the year 1008, it was plundered and burnt by Olof the Pious, king of Norway; in 1188, it was destroyed by the Carlians, Eitonians, and Russians. It recovered from these calamities, and flourished till the vast increase of Stockholm gave it a blow, which it is not likely to recover; 10 miles N. of Stockholm.

**SIGUA**, in *Ancient Geography*, a town of Asia, in the Greater Armenia. Ptolemy.

**SIGUENÇA**, in *Geography*, a city of Spain, in Old Castile, situated on the edge of a mountain, near the source of the river Henares; the see of a bishop, suffragan of Toledo, with an university, founded in the year 1441, by cardinal Ximenes. It contains three churches, three convents, two hospitals, a strong castle, an arsenal, and be-

tween 700 and 800 houses. This town was anciently called Segontia. A battle was fought here between Pompey and Sertorius; and in the beginning of the seventh century, the Goths were defeated here by the Romans; 56 miles N.E. of Madrid. N. lat. 40° 58'. W. long. 2° 57'.

**SIGUETTE**, in the *Manege*, is a cavesson of iron, with teeth or notches, that is, a semicircle of hollow and vaulted iron, with teeth like a saw, consisting of two or three pieces joined with hinges, and mounted with a head-stall and two ropes, as if they were the cavessons that in former times were wont to be put upon the nose of a fiery stiff-headed horse, in order to keep him in subjection.

There is a fort of figuette, that is, a round iron all of one piece, sewed under the nose-band of the bridle, that it may not be in view. This figuette we employ with a martingale, when a horse beats upon the hand.

**SIHASTRIA**, in *Geography*, a town of Moldavia; 34 miles W. of Suzava.

**SIHAUL**, a town on the W. coast of Sumatra. N. lat. 0° 25'. E. long. 119° 45'.

**SI-HIAM**, a town of China, of the third rank, in Chen-si; 37 miles E.S.E. of Han-tchong.

**SI-HO**, a town of China, of the third rank, in Chen-si; 42 miles W. of Oei.

**SI-HOA**, a town of China, of the third rank, in Ho-nan; 32 miles E.S.E. of Hiu.

**SIHON**, or **GIHON**, or *Amu*. See **JINON** and **AMU**.

**SIRON**, or *Sbarokiz*, a name given to the river Sirr, in its course.

**SIHOR**, a town of Hindoostan, in Guzerat; 25 miles W. of Gogo.

**SIHUTLA**, a town of Mexico, in the province of Mechoacan; 25 miles W. of Zacatula. N. lat. 18° 45'. W. long. 103° 26'.

**SIKAJOCKI**, a town of Sweden, in East Bothnia; 8 miles N. of Brahektad.

**SIKE**, in *Rural Economy*, a term provincially applied to a little rill, a water-furrow, and a gutter.

**SIKEVI**, in *Geography*, a town of Turkish Circassia, on the coast of the Black sea; 30 miles S.E. of Anapa.

**SIKFORD**, a town of Sweden, in West Bothnia; 18 miles N.W. of Pitea.

**SIKHS**, or **SEIKS**, an appellation formed of the Sanscrit term *Sikh*, or *Sicsha*, denoting a disciple or devoted follower, and in the Panjabi corrupted into *Sikh*, which is applicable to any person that follows a particular teacher; and hence used to denominate, in its primary use, a religious sect, which advanced, by successive gradations, from the humble condition of religionists, to the rank of one of the most powerful states in Hindoostan. The founder of this sect was Nanac Shah, a native of a small village called Talwandi, in the district of Bhatti, in the province of Lahore, where he was born A.D. 1469. It is now become a town, and denominated Rayapour, and is situated on the banks of the Beyah or Hyphasis. Nanac's father, whose name was Câlû, and who belonged to the Cshatriya cast and Védi tribe of Hindoos, wished to bring him up to trade, but Nanac himself was from his childhood inclined to devotion, and manifested an indifference to all worldly concerns. This disposition was cherished by his intercourse with the Fakirs, among whom and the poor he distributed a great part of his substance. It is needless to recite his trances and visions, and converse with the prophet Elias, and the austerities which he practised at the commencement and in the progress of his religious career. Nor can we accompany him in his travels which he undertook with a view of reforming the worship of the

the true God, that had been degraded by the idolatry of the Hindoos and the ignorance of the Mahometans. It will be sufficient for us to observe, that after he had visited all the cities of India, and explained to all ranks the great doctrines of the unity and omnipresence of God, he went to Mecca and Medina, where his actions, his miracles, and his long disputations with the Mahometan saints and doctors, are most circumstantially recorded by his biographers. He is stated, on this occasion, to have defended his own principles without offending those of others; always professing himself the enemy of discord, and as having no object but to reconcile the two faiths of the Mahometans and Hindoos in one religion; which he endeavoured to do by recalling them to that great and original tenet, which both of them believed, the unity of God; and by reclaiming them from the numerous errors into which they had fallen. During his travels, about the year 1526 or 1527, Nanac was introduced to the emperor Baber, before whom he is said to have maintained his doctrine with great firmness and eloquence. Baber treated him kindly, and offered him an ample maintenance, which the Sikh priest refused, alleging, that he trilled in him who provided for all men, and from whom alone a man of virtue and religion would consent to receive favour or reward. The Hindoo zealots violently opposed him, more especially after he had laid aside the habits of a Fakir; but he treated their opposition and reproaches with great contempt; and when they required him to exhibit some proof of his power, that might astonish them, he replied, "I have nothing to exhibit worthy of you to behold. A holy teacher has no defence but the purity of his doctrine; the world may change but the creator is unchangeable." Having migrated from Vatala to Multan, and from Multan to Kirtipur, on the banks of the Ravee or Hydraotis, he there performed many miracles, as it is reported, threw off his earthly shape, and was buried near the bank of the river Ravee, which has since overflowed his tomb. Kirtipur continues to be a place of religious resort and worship; and a small piece of Nanac's garment is exhibited to pilgrims, as a sacred relic, at his Dharmasala, or temple. Nanac was unquestionably a man of more than common genius, which we may infer from the distinguished eminence to which he attained, and the successes with which he combated the opposition that encountered him; whilst he laboured without intermission to recall both Mahometans and Hindoos to an exclusive attention to that sublimest of all principles, which inculcates devotion to God and peace towards men. Although he left two sons, he did not deem either of them worthy of a succession to his spiritual functions; but he devolved them upon a Chatriya of the Trehun tribe, called Lehana, whom he had initiated in the sacred mysteries of his sect, clothed in the holy mantle of a Fakir, and honoured with the name of Angad. Guru Angad was born at the village of Klandur, on the bank of the Beyah or Hyphafis, in the province of Lahore. He taught the same doctrine as Nanac; and some of his writings, as well as those of Nanac, are contained in a book entitled "Grant'h." At his death, which happened A.D. 1552, he was succeeded by Amera Das, a Chatriya of the tribe of B'halé, who had been a menial servant for twelve years. Amera Das was active in propagating the tenets of Nanac and successful in gaining profelytes, by whose assistance he established a degree of temporal power. He had two sons, and a daughter, named B'haini, who was married to a young lad, whose name was Ram Das, a Chatriya, of a respectable family, of the Sondi tribe, and an inhabitant of the village of Gondawal. Upon the death of Amera Das, A.D. 1574, he was succeeded by his son-in-law, whom he had initiated in the mysteries of his holy profession, and who became famous

for his piety, and still more on account of the improvements he made at Amritsar, which was for some time called Rampur, or Ramdasapur, after him. Some writers have erroneously ascribed the foundation of this town, anciently and long before his time denominated Chak, to him; however, he added much to its population, and built a famous tank, or reservoir of water, which he called Amritsar, a name signifying the water of immortality, and which has become so sacred, that it has given its name, and imparted its sanctity, to the town of Ramdasapur; so that it has become the sacred city of the Sikh nation, and is now only known by the name of Amritsar. After a life passed in the undisturbed propagation of his tenets, in explanation of which he wrote several books, Ram Das died A.D. 1581, and left two sons, one of whom, viz. Arjunmal, succeeded him, and rendered himself famous by compiling the A'di-Grant'h, containing ninety-two sections, part of which was composed by Nanac and his immediate successors, but arranged in its present form by Arjunmal, who blended his own additions with the compositions of his predecessors. Arjun, from this circumstance, is deemed the first who gave consistent form and order to the religion of the Sikhs. Arjun fell a sacrifice to the jealousy of the Mahometan government; and his death excited the indignation of the Sikhs, who, before this event, had been an inoffensive, peaceable sect; and they took up arms under Har Govind, the son of Arjunmal, and wreaked their vengeance upon all whom they thought concerned in the murder of their revered priest. From all the remaining accounts of Har Govind's life, it appears to have been his anxious wish to inspire his followers with the most irreconcilable hatred of their oppressors. Govind, with this view, introduced some change in their diet, allowing them to eat the flesh of animals, that of the cow excepted; and by other regulations converted a race of peaceable enthusiasts into an intrepid band of soldiers. Govind died A.D. 1644, and was succeeded by his grandson Har Ray, whose reign was upon the whole tranquil, which was probably owing to the vigour of the Mahometan power in the early part of the reign of Aurungzebe. At his death, A.D. 1661, a violent contest arose among the Sikhs, concerning the succession to the office of spiritual leader; for the temporal power of their ruler was, at this time, little more than nominal. The dispute was referred for decision to Delhi; and by an imperial decree of Aurungzebe, the Sikhs were allowed to elect their own priest. They chose Har Crihan, son (or grandson) of Har Ray, who died at Delhi A.D. 1664, and was succeeded by his uncle, Tegh Behadur. During his life, which terminated prematurely, by the violence of his rival, A.D. 1675, and also from the period of Govind's death, the Mogul empire was in the zenith of its power under Aurungzebe; and the Sikhs, who had never attained any real strength, were rendered still weaker by their own dissensions. However, after the death of Tegh Behadur, the history of the Sikhs assumed a new aspect. Under Har Govind the Sikhs had been initiated in arms, but they used them only in self-defence; but the plans of Govind's ambition were very different from those of his predecessor Nanac; and he wisely judged, that the only means by which he could ever hope to oppose the Mahometan government with success, were not only to admit converts from all tribes, but to break at once those rules by which the Hindoos had been so long chained;—to arm, in short, the whole population of the country, and to make worldly wealth and rank an object to which Hindoos, of every class, might aspire. It was the object of Govind to make all Sikhs equal, and that their advancement should solely depend upon their exertions; and well aware how necessary it was to inspire men of a low race,

and of grovelling minds, with pride in themselves, he changed the name of his followers from Sikh to Sinh or lion; thus giving to all his followers that honourable title which had been before exclusively assumed by the Rajaputs, the first military class of Hindoos; and every Sikh felt himself at once elevated, by this proud appellation, to a footing with the first class. The disciples of Govind were required to devote themselves to arms; always to have steel about them in one shape or other; to wear a blue dress; to allow their hair to grow; and to exclaim, when they met each other, "Wa! Guruji ka khalfat! Wa! Guruji ki futteh!" *i. e.* Success to the state of the Guru! Victory attend the Guru! Guru Govind inculcated his tenets upon his followers by his preaching, his actions, and his works. He is said to have first instituted the Guru-mata, or state council, among the Sikhs, which meet at Amritsar; by which institution he gave that form of a federative republic to the commonwealth of the Sikhs, which was most calculated to rouse his followers from their indolent habits, and deep-rooted prejudices, by assigning to them a personal share in the government, and placing within the reach of every individual, the attainment of rank and influence in the state. The emperor Aurungzebe, aided by the rajas who were hostile to Govind, pursued him and his followers to Chamkour, and encompassed it on all sides. The siege was carried on with great vigour; and though Govind manifested an invincible spirit, and performed prodigies of valour, he was at last overpowered by numbers; and reduced to the necessity of making his escape from Chamkour in a dark night, covering his face, as it is said, from shame at his own disgrace. After his flight, a sense of his misfortunes, and the loss of his children, deprived him of his reason, and he wandered about for a considerable time in the most deplorable condition. At length, having obtained from the emperor Behadur Shah a small military command in the Deccan, he was stabbed by a Patan soldier's son, and expired of his wounds, A.D. 1708, at Naded, a town situated on the Caveri river, about 100 miles from Haiderabad. Guru Govind was the last acknowledged religious ruler of the Sikhs. A prophecy had limited their spiritual guides to the number of ten; and their superstition, aided, without doubt, by the action of that spirit of independence which his institutions had introduced, caused its fulfilment. Banda, a devoted follower and friend of Guru Govind, established the union of the Sikhs under his banners; and his grief at the misfortune of his priest, is said to have settled after the death of Govind into a gloomy and desperate desire to avenge his wrongs. The confusion which took place on the death of Aurungzebe, which happened A.D. 1707, was favourable to his wishes. Having obtained a victory over the Mahometans in a bloody action, Banda, encouraging the Sikhs, and hardening them by his lessons to deeds of the most horrid atrocity, subdued all the country between the Setlej and the Jumna, and crossing that river, made inroads into the province of Sharanpour, which lies a few miles to the N.E. of Delhi, between the rivers Jumna and the Ganges. The march of the Sikhs was attended with the exercise of the most wanton barbarity; life was only granted to those who conformed to the religion, and adopted the habits and dress of the Sikhs; and if Behadur Shah had not quitted the Deccan, which he did A.D. 1710, the whole of Hindoostan would probably have been subdued by these merciless invaders. The first check which the Sikhs received was from an army under sultan Kuli Khan. They were afterwards defeated in a very desperate action by Abdal Samad Khan, an officer of the emperor Farakhseir, after which the Sikhs were never able to make a stand, but were hunted like wild beasts from one strong hold to another,

by the army of the emperor, by whom their leader, Banda, and his most devoted followers, were at last taken, after having suffered every extreme of hunger and fatigue. Great numbers of the Sikhs were put to death, after the surrender of Lohgad, a fortress 100 miles N.E. of Lahore; but Banda was sent, with the principal chiefs of the tribe, to Delhi, where, after having been treated with every kind of obloquy and insult, they were executed.

After the defeat and death of Banda, resentment prompted to every measure that could be devised, not only to destroy the power, but to extirpate the race of the Sikhs. From the Mahometans they met with no quarter; and after the execution of their chief, a royal edict was issued, ordering all who professed the religion of Nanac to be taken and put to death wherever found; and by way of giving greater effect to this mandate, a reward was offered for the head of every Sikh. During the interval that elapsed between the defeat and death of Banda, and the invasion of India by Nadir Shah, a period of nearly 30 years, we hear nothing of the Sikhs; but when that event occurred, they are said to have fallen upon the inhabitants of the Panjab, who sought shelter in the hills, and to have plundered them of that property which they were endeavouring to secure from the rapacity of the Persian invader. Enriched with these spoils, says the author whose account of them we are now citing, the Sikhs left the hills, and built the fort of Dalewal, on the Ravi, from whence they made predatory incursions, and are stated to have added, both to their wealth and reputation, by harassing and plundering the rear of Nadir Shah's army, which, when it returned to Persia, was encumbered with spoil, and marched, from a contempt of its enemies, with a disregard to all order.

The weak state to which the empire of Hindoostan was reduced, and the confusion into which the provinces of Lahore and Cabul were thrown, by the death of Nadir, were events of too favourable a nature to the Sikhs to be neglected by that race, who became daily more bold, from their numbers being greatly increased by the union of all those who had taken shelter in the mountains; the re-admission into the sect of those who, to save their lives, had abjured, for a period, their usages; and the conversion of a number of proselytes, who hastened to join a standard under which robbery was made sacred, and to plunder was to be pious.

Aided with these recruits, the Sikhs now extended their irruptions over most of the provinces of the Panjab; and though it was some time before they repossessed themselves of Amritsar, they began, immediately after they quitted their fastnesses, to flock to that holy city at the periods of their sacred feasts. Some performed this pilgrimage in secret, and in disguise; but in general, according to a contemporary Mahometan author, the Sikh horsemen were seen riding, at full gallop, towards "their favourite shrine of devotion. They were often slain in making this attempt, and sometimes taken prisoners; but they used, on such occasions, to seek, instead of avoiding, the crown of martyrdom:" and the same authority states, "that an instance was never known of a Sikh, taken in his way to Amritsar, consenting to abjure his faith."

Encouraged by the confusion which took place on the first Afghan invasion, A.D. 1746, the Sikhs made themselves masters of a considerable part of the Dooab of Ravi and Jalandra, and the country between the rivers Ravi and Beyah, and that river and the Setlej, and extended their incursions to the neighbouring countries. But though they were severely and repeatedly checked by Mir Mannu, the governor of Lahore, yet, after his death, they availed themselves of all the advantages which the local distractions of a falling empire

pire afforded them of extending and establishing their power. Their bands, under their most active leaders, plundered in every direction, and were successful in obtaining possession of several countries, from which they have never since been expelled; and their success, at this period, was promoted, instead of being checked, by the appointment of their old friend, Adina Beg Khan, to Lahore; as that brave chief, anxious to defend his own government against the Afghans, immediately entered into a confederacy with the Sikhs, whom he encouraged to plunder the territories of Ahmed Shah Abdali.

The Afghan monarch, resenting this predatory warfare, in which the governor of Lahore was supported by the court of Delhi, determined upon invading India. Adina Beg, unable to oppose him, fled: and the Sikhs could only venture to plunder the baggage, and cut off the stragglers of the Afghan army, by which they so irritated Ahmed Shah, that he threatened them with punishment on his return; and when he marched to Cabul, he left his son Taimur Khan, and his vizir, Jehan Khan, at Lahore, with orders to take vengeance on the Sikhs for all the excesses which they had committed. The first expedition of Taimur Khan was against their capital, Amritsar, which he destroyed, filling up their sacred tank, and polluting all their places of worship; by which action he provoked the whole race to such a degree, that they all assembled at Lahore, and not only attempted to cut off the communication between the fort and country, but collected and divided the revenues of the towns and villages around it. Taimur Khan, enraged at this presumption, made several attacks upon them, but was constantly defeated; and, being at last reduced to the necessity of evacuating Lahore, and retreating to Cabul, the Sikhs, under one of their celebrated leaders, called Jassa Singh Calal, immediately took possession of the vacant soubah of Lahore, and ordered rupees to be coined, with an impression to the following import: "Coined by the grace of Khalfah ji, in the country of Ahmed, conquered by Jassa Singh Calal." Although they were afterwards expelled, together with the Afghans, from Lahore, yet after the death of Adina Beg Khan, the governor of this province, they eagerly seized the opportunity that was thus afforded them, of making themselves again masters of Lahore. Their success was, however, soon checked by Ahmed Shah Abdali, who, irritated by their unsubmitting turbulence and obstinate intrepidity, made every effort (after he had gained the victory of Panipat, which established his supremacy at Delhi) to destroy their power; and, with this view, he entered the Panjab early in 1762, and over-ran the whole of that country with a numerous army, defeating and dispersing the Sikhs in every direction. That sect, unable to make any stand against the army of the Abdali, pursued their old plan of retreating near the mountains; and collected a large force in the northern districts of Sirhind, a distance of above one hundred miles from Lahore, where the army of Ahmed Shah was encamped. Here they conceived themselves to be in perfect safety; but that prince made one of those rapid movements for which he was so celebrated, and reaching the Sikh army on the second day, completely surprised and defeated it with great slaughter. In this action, which was fought in February 1762, the Sikhs are said to have lost upwards of twenty thousand men; and the remainder fled into the hills, abandoning all the lower countries to the Afghans, who committed every ravage that a barbarous and savage enemy could devise. Amritsar was razed to the ground, and the sacred reservoir again choaked with its ruins. Pyramids were erected, and covered with the heads of slaughtered Sikhs; and it is mentioned that Ahmed Shah caused

the walls of those mosques which the Sikhs had polluted to be washed with their blood, that the contamination might be removed, and the insult offered to the religion of Mohamet expiated.

This species of savage retaliation appears to have animated instead of depressing the courage of the Sikhs, who, though they could not venture to meet Ahmed Shah's army in action, harassed it with an incessant predatory warfare; and when that sovereign was obliged, by the commotions of Afghanistan, to return to Cabul, they attacked and defeated the general he had left in Lahore, and made themselves masters of that city, in which they levelled with the ground those mosques which the Afghans had, a few months before, purified with the blood of their brethren.

When Ahmed Shah, after retaking Lahore, A.D. 1763, was obliged, in the ensuing year, to return to his own country, the Sikhs again expelled his garrison, and made themselves masters of the Panjab; and, from that period until his death, a constant war was maintained, in which the enterprize and courage of the Afghans gradually gave way before the astonishing activity, and invincible perseverance, of their enemies; who, if unable to stand a general action, retreated to impenetrable mountains, and the moment they saw an advantage, rushed again into the plains with renewed vigour and recruited numbers. Several Sikh authors, treating of the events of this period, mention a great action having been fought by their countrymen, near Amritsar, against the whole Afghan army, commanded by Ahmed Shah in person; but they differ with regard to the date of this battle, some fixing it in 1762, and others later. They pretend that the Sikhs, inspired by the sacredness of the ground on which this action was fought, contended for victory against superior numbers with the most desperate fury, and that the battle terminated in both parties quitting the field, without either being able to claim the least advantage. The historians of Ahmed Shah are, however, silent regarding this action, which indeed, from all the events of his long contests with the Sikhs, appears unlikely to have occurred. It is possible the Sikhs fought at Amritsar with a division of the Afghan army, and that might have been commanded by the prince; but it is very improbable they had ever force to encounter the concentrated army of the Abdalis, before which, while it remained in a body, they appear, from the first to the last of their contests with that prince, to have always retreated, or rather fled.

The Sikhs, when oppressed, became as formidable for their union, as for their determined courage and unconquerable spirit of resistance: but a state of persecution and distress was most favourable for a constitution like theirs, which required constant and great sacrifices of personal advantage to the public good; and such sacrifices can only be expected from men who act under the influence of that enthusiasm, which the fervour of a new religion, or a struggle for independence, only imparts, and which are always most readily made when it becomes obvious to all, that a complete union in the general cause is the only hope of individual safety.

The Sikhs may be reckoned the most western nation of Hindoostan: for the king of Candahar possesses but an inconsiderable extent of territory on the east of the Indus. Since the complete downfall of the Mogul empire, they have acquired very extensive domains. But major Rennell observes, that their power ought not to be estimated in the exact proportion to the extent of their population, since they do not form one entire state; but a number of small ones, independent of each other in their internal government, and only connected by a federal union. They have extended their territories on the south-east, that is, into the province

of Delhi, very rapidly of late years; and perhaps, the Zemindars of that country may have found it convenient to place themselves under the protection of the Sikhs, in order to avoid the more oppressive government of their former masters. It is certain that the eastern boundary of the Sikhs' dominions has been advanced to the banks of the Jumnah river, above Delhi, and to the neighbourhood of that city; for the adjoining territory of Schaurunpour is subject to their depredations, if not actually tributary to them; and they make incursions even to the side of the Ganges. On the south, they are bounded by the northern extreme of the sandy desert of Registan, and on the south-west their boundary meets that of Sindy, or Tatta, at the city of Behker or Bhekr, on the Indus. On the west the Indus is their general boundary, as high up as the city of Attock; near to which begin the territories of the king of Candahar; and their northern boundary is the chain of mountains that lies towards Thibet and Cashmere. As this is the case, they will be found to possess the whole soubah or province of Lahore, the principal part of Moultan, and the western part of Delhi; the dimensions of which tract are about 400 British miles from N.W. to S.E., and from 150 to 200 broad, in general; although in the part between Attock and Belker (that is, along the Indus) the extent cannot be less than 320. Their capital city is Lahore.

According to the statement of brigadier-general Malcolm, the country now possessed by the Sikhs, which reaches from N. lat.  $28^{\circ}40'$  to beyond N. lat.  $32^{\circ}$ , and includes all the Panjab, a small part of Moultan, and most of that tract of country which lies between the Jumnah and the Setlej, is bounded, to the northward and westward, by the territories of the king of Cabul; to the eastward, by the possessions of the mountaineer rajas of Jammu, Nadon, and Srinagar; and to the southward, by the territories of the English government, and the sandy deserts of Jafalmer and Hansya Hifar. A general estimate of the value of the country possessed by the Sikhs may be formed, when it is stated, that it contains, besides other countries, the whole of the province of Lahore; which, according to Mr. Bernier, produced in the reign of Aurungzebe, 246 lacks and 95,000 rupees; or 2,469,500*l.* sterling. The Sikhs who inhabit the country between the Setlej and the Jumnah, are called Malwa Sinh, and were almost all converted from the Hindoo tribes of Jats and Gujars. The country of the Malwa Sinh is in some parts fruitful; but those districts which border on Hansya and Carnal are very barren; being covered with low wood, and in many places almost destitute of water. Its former capital was Sirhind, but it is now a complete ruin. Patiala is now the largest and most flourishing town of this province, and next to it is T'hanesur, which is still held in high veneration by the Hindoos, who have also a high reverence for the river Serafweti, which flows through this province. The country of Jalendra Dooab, which reaches from the mountains to the junction of the Setlej and the Beah, is the most fruitful of all the possessions of the Sikhs, and is perhaps excelled, in climate and vegetation, by no province in India. The soil is light, but very productive; the country, which is open and level, abounds in every kind of grain. The towns of Jalendra and Sultanpour are the principal in the Dooab. The country between the Beyah and Ravi rivers is called Bari Dooab, or Manj'ha; and the Sikhs inhabiting it are called Manj'ha Sinh. The cities of Lahore and Amritsar are both in this province, and consequently it becomes the great centre of the power of this nation. The country of Bari is said to be less fertile, particularly towards the mountains, than Jalendra, but lying on the same level, its climate and soil must be nearly the same.

The inhabitants of the country between Ravi and Chanhab are called D'harpi Sinh, from D'harpi, the name of the country; the D'hanigheb Sinh are beyond the Chanhab, but within the Jehalam river. The Sind Sinh is the term by which the inhabitants of the districts under the Sikhs bordering on the Sind are known; and Nakai Sinh is the name given to the Sikhs who reside in Moultan.

The government of the Sikhs may be termed a theocracy. Although they obey a temporal chief, that chief preserves his power and authority by professing himself the servant of the khalsa, or government, which can only be said to act, in times of great public emergency, through the means of a national council, of which every chief is a member, and which is supposed to deliberate and resolve under the immediate inspiration and impulse of an invisible being; who, as they believe, always watches over the interests of the commonwealth. It is natural, however, to imagine that the power of this assembly should decline; and from Col. Malcolm's account, we may infer, that it is nearly destroyed. The last Guru-mata was called in 1805, when the British army pursued Holkar into the Panjab. The government is mild; but in their mode of making war the Sikhs are unquestionably savage and cruel. Among the Sikhs there is a class of devotees, called Acalis, or immortals, who, under the double character of fanatic priests and desperate soldiers, have usurped the sole direction of all religious affairs at Amritsar; and who, of course, are leading men in a national council held at that sacred place, and which deliberates under all the influence of religious enthusiasm. This order of Sikhs was first founded by Guru Govind, and are distinguished by their dress, as well as by their having almost the sole direction of the religious ceremonies at Amritsar. They have a place on the bank of the sacred reservoir of Amritsar, where they generally resort, but are individually possessed of property, though they affect poverty, and subsist on charity. The principal chiefs of the Sikhs are all descended from Hindoo tribes. The lower order of Sikhs, compared with the wretched Mahometans who are doomed to oppression and hard labour, are happy; they are protected from the tyranny and violence of the chiefs under whom they live by the precepts of their common religion, and by the condition of their country, which enables them to abandon, whenever they chuse, a leader whom they dislike. The civil officers, to whom the chiefs entrust their accounts, and the management of their property and revenue concerns, as well as the conduct of their negotiations, were in general Sikhs of the Khalasa cast, who, being followers of Nanac, and not of Guru Govind, are not devoted to arms, but educated for peaceful occupations, in which they often become very expert and intelligent. In the collection of the revenue of the Panjab, it is said to be a general rule, that the chiefs to whom the territories belong should receive the half of the produce, grain paying in kind, but sugar, melons, &c. in cash, and the farmer the other; but the chief never levies the whole of his share; and in no country, perhaps, is the ryat, or cultivator, treated with more indulgence. Commerce is rather restrained than encouraged by the heavy duties and the distracted state of the country. However, a great part of the shawl trade now flows through the cities of Lahore, Amritsar, and Patiala, to Hindoostan. The administration of justice among the Sikhs is in a very rude and imperfect state.

Their law is all unwritten. Nothing is consigned to any express form of words. There is no definition of any thing. The custom of the country, the custom of the court, (that is to say, as far as the judge is pleased to be governed by those customs), and the will of the judge,—are the

the circumstances which guide the decision. Among the Hindoos some of the sacred books, among the Mahometans the Koran, are used as the books of law. Among the Sikhs there is no such reference to any sacred books; and their situation is, in all probability, so much the better: for the Koran or Hindoo books afford scarcely any rules or principles of law, which are not so vague as to speak any language which the interpreter chuses to give them; and while their authority is sufficient to supersede that of the natural dictates of justice and equity, which are the only guides of the Sikh judges, the Hindoo or Mahometan has only to fisd or to feign a principle of his book, which may enable him to decide as he pleases.

Trifling disputes about property are settled by the heads of the village, by arbitration, or by the chiefs. The court of arbitration is called *panchayat*, or a court of five, the general number of arbitrators chosen to adjust differences and disputes. It is usual to assemble a panchayat, or a court of arbitration, in every part of India under a native government; and, as they are always chosen from men of the best reputation in the place where they meet, this court has a high character for justice. The decision obtained by either of these modes is final. If a theft occurs, the property is recovered, and the party punished, not with death, by the person from whom it was stolen, or by the inhabitants of the village, or his chief. Murder is sometimes punished by the chief; but more generally by the relatives of the deceased, who, in such cases, rigorously retaliate on the murderer, and sometimes on all who endeavour to protect him.

The character of the Sikhs, or rather Sinhs, which is the name by which the followers of Guru Govind, who are all devoted to arms, are distinguished, is very marked. They have, in general, the Hindoo cast of countenance, somewhat altered by their long beards, and are to the full as active as the Mahrattas, and much more robust, from their living fuller, and enjoying a better and colder climate. Their courage is equal at all times to that of any natives of India; and when wrought upon by prejudice or religion, is quite desperate. They are all horsemen, and have no infantry in their own country, except for the defence of their forts and villages, though they generally serve as infantry in foreign armies. They are bold, and rather rough in their address, which appears more to a stranger from their invariably speaking in a loud tone of voice: but this is quite a habit, and is alike used by them to express the sentiments of regard and hatred. The Sikhs have been reputed deceitful and cruel, but Sir John Malcolm knew no grounds upon which they could be considered more so than the other tribes of India: they seemed to him, from all the intercourse he had with them, to be more open and sincere than the Mahrattas, and less rude and savage than the Afghans. They have, indeed, become, from national success, too proud of their own strength, and too irritable in their tempers, to have patience for the wiles of the former: and they retain, in spite of their change of manners and religion, too much of the original character of their Hindoo ancestors, (for the great majority are of the Hindoo race,) to have the constitutional ferocity of the latter. The Sikh soldier is, generally speaking, brave, active, and cheerful; without polish, but destitute neither of sincerity nor attachment; and, if he often appears wanting in humanity, it is not so much to be attributed to his national character, as to the habits of a life, which, from the condition of the society in which he is born, is generally full in scenes of violence and rapine.

The Sikh merchant, or cultivator of the soil, if he is a Sinh, differs little in character from the soldier, except that his occupation renders him less presuming and boisterous.

He also wears arms, and is, from education, prompt to use them, whenever his individual interest, or that of the community in which he lives, requires him to do so. The general occupations of the Khalafa Sikhs has been before mentioned. Their character differs widely from that of the Sinhs. Full of intrigue, pliant, versatile, and insinuating, they have all the art of the lower classes of Hindoos, who are usually employed in transacting business; from whom, indeed, as they have no distinction of dress, it is very difficult to distinguish them.

The general character of the religious tribes of Acalis, Shahid, and Nirmala, is formed from their habits of life. The Acalis are insolent, ignorant, and daring; presuming upon those rights which their numbers and fanatic courage have established, their deportment is hardly tolerant to the other Sikhs, and insufferable to strangers, for whom they entertain a contempt which they take little pains to conceal. The Shahid and the Nirmala, particularly the latter, have more knowledge and more urbanity; they are almost all men of quiet, peaceable habits; and many of them are said to possess learning.

There is another tribe among the Sikhs, called the Nanae Pautra, or descendants of Nanae, who have the character of being a mild, inoffensive race; and though they do not acknowledge the institutions of Guru Govind, they are greatly revered by his followers, who hold it sacrilege to injure the race of their founder; and, under the advantage which this general veneration affords them, the Nanae Pautra pursue their occupations; which, if they are not mendicants, is generally that of travelling merchants. They do not carry arms; and profess, agreeably to the doctrine of Nanae, to be at peace with all mankind.

The Sikh converts continue, after they have quitted their original religion, all those civil usages and customs of the tribes to which they belonged, that they can practise, without infringement of the tenets of Nanae, or the institutions of Guru Govind. They are most particular with regard to their intermarriages; and on this point, Sikhs descended from Hindoos almost invariably conform to Hindoo customs, every tribe intermarrying within itself. The Hindoo usage regarding diet, is also held equally sacred; no Sikh descended from a Hindoo family ever violating it, except upon particular occasions, such as a Guru-mata, when they are obliged, by their tenets and institutions, to eat promiscuously. The strict observance of these usages has enabled many of the Sikhs, particularly of the Jat and Gujar tribes, which include almost all those settled to the south of the Setlej, to preserve an intimate intercourse with their original tribes; who, considering the Sikhs not as having lost cast, but as Hindoos that have joined a political association, which obliges them to conform to general rules established for its preservation, neither refuse to intermarry, nor to eat with them.

We shall here add, that the "Jats" are Hindoos of a low tribe, who, taking advantage of the declining state of the Mogul empire, have, by their courage and enterprise, raised themselves to some consequence on the north-western parts of Hindoostan, and many of the strongest forts of that part of India are still in their possession. The "Gujars" are also Hindoos, and have raised themselves to power by means not dissimilar to those used by the Jats. Almost all the thieves in Hindoostan are of this tribe.

The higher cast of Hindoos, such as Brahmens and Chatriyas, who have become Sikhs, continue to intermarry with converts of their own tribes, but not with Hindoos of the cast they have abandoned, as they are polluted by eating animal food, all kinds of which are lawful to Sikhs, except the cow, which it is held sacrilege to slay.

The Mahometans, who become Sikhs, intermarry with each other, but are allowed to preserve none of their usages, being obliged to eat hog's flesh, and abstain from circumcision.

The Sikhs are forbidden the use of tobacco, but allowed to indulge in spirituous liquors, which they almost all drink to excess; and it is rare to see a Sinh soldier, after sunset, quite sober. Their drink is an ardent spirit, made in the Panjab; but they have no objection to either the wine or spirits of Europe, when they can obtain them.

The use of opium to intoxicate is very common with the Sikhs, as with most of the military tribes of India. They also take b'hang (*cannabis fativa*), another inebriating drug.

The conduct of the Sikhs to their women differs in no material respect from that of the tribes of Hindoos, or Mahometans, from whom they are descended: their moral character, with regard to women, and indeed in most other points, may, from the freedom of their habits, generally be considered as much more lax than that of their ancestors, who lived under the restraint of severe restrictions, and whose fear of excommunication from their cast, at least obliged them to cover their sins with the veil of decency. This the emancipated Sikhs despise; and there is hardly an infamy which this debauched and dissolute race are not accused, and with justice, as sir John Malcolm believed, of committing in the most open and shameful manner.

The Sikhs are almost all horsemen, and they take great delight in riding. Their horses were formerly famous for their strength, temper, and activity; but they are now no better mounted than the Mahrattas.

Their horsemen use swords and spears, and most of them now carry match-locks, though some still use the bow and arrow, a species of arms for excellence in the use of which their forefathers were celebrated, and which their descendants appear to abandon with great reluctance.

The education of the Sikhs renders them hardy, and capable of great fatigue; and the condition of the society in which they live, affords constant exercise to that restless spirit of activity and enterprise which their religion has generated. Such a race cannot be epicures; they appear, indeed, generally to despise luxury of diet, and pride themselves in their coarse fare. Their dress is also plain, not unlike the Hindoos, equally light, and divested of ornament. Some of the chiefs wear gold bangles, but this is rare; and the general characteristic of their dress and mode of living is simplicity.

The principal leaders among the Sikhs affect to be familiar and easy of intercourse with their inferiors, and to despise the pomp and state of the Mahometan chiefs; but their pride often counteracts this disposition; and they appear to have, in proportion to their rank and consequence, more state, and to maintain equal, if not more reserve and dignity with their followers, than is usual with the Mahratta chiefs.

It would be difficult, if not impracticable, to ascertain the amount of the population of the Sikh territories, or even to compute the number of the armies which they could bring into action. They boast that they can raise more than a hundred thousand horse; and, if it were possible to assemble every Sikh horseman, this statement might not be an exaggeration; but there is, perhaps, no chief among them, except Ranjit Sinh, of Lahore, that could bring an effective body of four thousand men into the field; and the force of Ranjit Sinh did not, in 1805, amount to eight thousand, and part of that was under chiefs who had been subdued from a state of independence, and whose turbulent minds ill-brooked an usurpation, which they deemed sub-

versive of the constitution of their commonwealth. His army is now more numerous than it was, but it is composed of materials that have no natural cohesion, and the first serious check which it meets will probably cause its dissolution.

As for the religion of the Sikhs, it seems, says sir John Malcolm, to have been a sort of pure deism, grounded on most sublime general truths, blended with the belief of all the absurdities of the Hindoo mythology, and the fables of Mahometanism; for Nanac professed to conciliate Hindoos and Mahometans to the belief of his doctrine, by persuading them to reject those parts of their respective belief and usages, which, he contended, were unworthy of that God whom they both adored. He endeavoured to impress both Hindoos and Mahometans with a love of toleration, and an abhorrence of war; and his life was as peaceable as his doctrine.

We cannot forbear remarking on the inconsistency and contradiction which are involved in the idea of "pure deism" blended with the belief of absurdities. As well might we call a system of philosophy perfect, the greater part of which is nonsense. Is it not evident, says an anonymous writer, that so far as absurdities are mixed with a religious creed, so far the purity of its deism is excluded.—But to proceed; Guru Govind, as we have already suggested, gave a new character to the religion of his followers, by establishing institutions and usages, which not only separated them from other Hindoos, but which, by a complete abolition of all distinctions of casts, destroyed a system of civil polity, which, from being interwoven with the religion of a weak and bigotted race, fixed the rule of its priests upon a basis that had withstood the shock of ages. For further particulars we must refer to the author, whose elaborate account of the Sikhs has furnished the principal materials of this article. Malcolm's Sketch of the Sikhs, in vol. xi. of the Asiatic Researches; or Sketch of the Sikhs, &c. London, 1812. Rennell's Memoir, Introd. Edin. Rev. No. 42.

SIKI, in *Geography*, a town of Asiatic Turkey, in Carmania, on the Draganto; 27 miles W. of Selekeh.

SI-KIANG, or *West River*, a river of China, which rises near Fong-tcheou, in Quang-tong, and runs into the sea, S. of Canton.

SIKIATZKOI, a town of Russia, on the Lena; 140 miles N. of Ziganst. N. lat.  $69^{\circ} 20'$ . E. long.  $121^{\circ} 40'$ .

SIKINOS, an island in the Grecian Archipelago, which lies seven or eight miles to the W.S.W. of Nio. This island is lofty and mountainous, of small extent, being about twenty miles in circumference, and contains, according to Olivier, no more than 200 inhabitants. It has no harbour, and is now little frequented by Europeans. Its productions consist of wheat, barley, wine, cotton, and fruits. It pays about 2000 piastres to the captain-pacha. A town of the same name with the island is situated on a rock, which hangs over the sea. N. lat.  $36^{\circ} 43'$ . E. long.  $25^{\circ} 10'$ .

SIKKE. See SIGG.

SIKNA, a river of Moldavia, which runs into the Zita, 20 miles S.W. of Batufzani.

SIKOKO. See XICOCO.

SIKOVVOE, a small island in the East Indian sea. S. lat.  $7^{\circ} 12'$ . E. long.  $131^{\circ} 51'$ .

SIL, a river of Switzerland, which runs into the Limat, one mile below Zurich.—Also, a river of Spain, in Galicia, which rises in the mountains to the west of Leon, where it receives the Beza and the Burvia in Galicia, passes on to San-Estevan and to Torbe, where it receives the Lor, and  
in

in its turn falls into the Mino; its course is thirty-three leagues.

**SIL**, in *Canals*, the bottom timber of sluices, lock-gates, &c.

**SIL**, in *Natural History*, a name given by the ancients to a red ochre, of which they had three distinct kinds, the *fil syricum*, *fil atticum*, and *fil marmorosum*; all of which are to be had at this time, and all very valuable paints.

**SIL Syricum** is a substance well known among the painters of the present age, though not by name, being the red ochre, commonly used for a purple colour in their coarser works; though it is capable of yielding, by proper management, a colour fit for their finest. It is very heavy, and of a fine strong red, with some tendency to purple, of a loose friable texture, and very rough and dusty surface. It adheres firmly to the tongue, is somewhat soft to the touch, crumbles easily to pieces between the fingers, and stains the hands very much. It melts freely in the mouth, and has a strongly astringent taste. It burns to a much paler colour, and makes no effervescence with aqua fortis. These are the characters by which this is distinguished from all the other red earths. It is dug in many parts of England, and is sent to London in great quantities. Hill.

**SIL Atticum** is the purple ochre, called in later times *almagra*.

**SIL Marmorosum** is also a substance in some degree known in the world at this time. It sometimes falls into the hands of our painters, who call it Indian stone-red, but it has many other valuable qualities extremely worth enquiring into. It is the hardest and driest of all the ochres, and while in the stratum appears absolutely stony, forming thin, flat, regular strata, and is so hard, that it is not to be dug without the pick-axe; it is also of an obscurity and irregularly laminated structure, and naturally breaks into flat pieces. It is of a fine purplish-red, and very heavy, and contains a multitude of fragments of a fine lead-ore, which are bright and blueish, and makes a very pretty appearance, and beside these has always among it a small quantity of pure native cinnabar; both these substances are so nicely mixed with it, that it is scarcely possible to break off a piece of an inch square from any part of the strata that has not more or less of both in it. It is of a dusty surface, and rough to the touch, and adheres very firmly to the tongue, and stains the hands. It is of a very austere and astringent taste, and makes no effervescence with acids. There are considerable strata of it on the borders of China, and it is much used as a paint in the East Indies. There is some of it at times brought over to us, but not enough to make it a regularly marketable commodity. Beside its use as a paint, it is worth enquiring into on account of the cinnabar it contains; three ounces of it having yielded, on trial, two drachms and a scruple of pure quicksilver. Hill.

**SILA**, in *Ancient Geography*, a forest of Italy, in Brutium, N. of the town of Rhegium, occupying part of the Apennines. Strabo.—Also, a town situated at a considerable distance from Japygia.

**SILACH**, a word used by medical authors for a disorder of the eye-lid, consisting in a preternatural thickens of it, or a swelling without inflammation.

**SILADING**, in *Geography*, a small island in the East Indian sea, near the N. coast of Celebes. N. lat.  $1^{\circ} 21'$ . E. long.  $124^{\circ} 25'$ .

**SILÆ**, in *Ancient Geography*, a town situated in the interior of Arabia Felix. Ptol.

**SILAH-ETCHAUK**, in *Geography*, a town of Bengal; 25 miles N.W. of Ramgur.

VOL. XXXII.

**SILAI**, a town of Hungary; 32 miles S. of Zatzmar.

**SILAMBOE**, a town on the S. coast of the island of Java. S. lat.  $7^{\circ} 33'$ . E. long.  $107^{\circ} 15'$ .

**SILANDAM**, in *Ancient Geography*, a town of Asia Minor, in Lycia.

**SILARUS**, a river of Italy, which commenced in the territory of the Hirpini, separated the Picentini from Lucania, and discharged itself into the sea near Paestum. Strabo says, that this river petrified the plants that were thrown into it, without destroying their colour or their form.—Also, a mountain of Italy, in Lucania.

**SILAS**, a river of India, which sprung from a fountain of the same name, and ran into the country of the Siléans, according to Arrian.

**SILATUM**, a word used by the ancient Romans to express a morning's draught of wine. This was usually of a wine medicated with the plant sili, or fesceli, and thence had its name. It has always been the custom to medicate the morning draughts of any strong liquor; we do it with wormwood, or the common bitter tincture; the Indians with ginger.

**SILAVENGO**, in *Geography*, a town of Italy, in the Novarese; 10 miles N.W. of Novara.

**SILAUM**, in *Botany*, a name used by some authors for the *saxifraga pratensis*, or common meadow saxifrage.

**SILAUNA**, in *Geography*, a town of European Turkey, in Bulgaria; 40 miles W. of Nicopoli.

**SILBACH**, a village of Westphalia, in which is found lead-ore mixed with silver; 12 miles S. of Brilon.

**SILBE**, a town of Africa, in the country of the Foolahs, on the Senegal. N. lat.  $17^{\circ} 5'$ .

**SILBERBACH**, a town of Prussia, in the province of Oberland; 6 miles W. of Liebstadt.

**SILBERBERG**, a mine-town of Silesia, belonging to the principality of Brieg, but insulated in that of Munsterberg. N. lat.  $50^{\circ} 24'$ . E. long.  $16^{\circ} 26'$ .

**SILBEREGG**, a town of the duchy of Carinthia; 2 miles N.W. of Eberstein.

**SILBERMANN, JOHANN ANDREAS**, in *Biography*, the most eminent and renowned organ-builder and maker of keyed-instruments in Germany. He was born at Strasburg in 1712, and the first of a numerous and eminent family of that name, who have inherited his professional abilities and reputation. There is, in Gerber's Continuation of Walther's Musical Lexicon, a list of their several names and works; but old Silbermann was the *Father Smith* of Germany. His instruments are prized above all others for workmanship and tone. The Bach family have been always partial, not only to Silbermann's organs, but harpsichords and clavichords. When we heard Emanuel Bach perform at Hamburg, it was always on a favourite Silbermann clavichord; piano fortes were not then brought to great perfection any where; but since that time we find that John Henry Silbermann is much celebrated for his piano fortes.

**SILBERSCHLAG, JOHN ISAIAH**, a German mathematician and mechanist, was born in 1721. He studied at the college Klosterberge, near Magdeburg, and afterwards went through a course of theology at Halle, from which place he returned to the college at which he had been before, where he taught natural philosophy and mathematics for nine years. After this he became pastor of one of the churches at Berlin, and rector of the royal school. He was a member of the Academy of Sciences in that city; and, besides writing various works on mechanical and mathematical subjects, constructed a great many machines, instruments, and models, for the use of the students in the seminary which had been placed under his care. He died

in November 1791. He left behind him a great number of works, among which are, "A Treatise on the warlike Machines of the Ancients;" "Letters on the Northern Lights;" "A Treatise on Hydraulic Architecture;" "The Chronology of the World rectified by the Scriptures." Gen. Biog.

SILBERSTRASS, in *Geography*, a town of Saxony, in the circle of Erzgebirg; 4 miles S.S.E. of Zwickau.

SILBIUM, in *Ancient Geography*, a town of Italy, in Japygia.—Also, a town of Asia, in Greater Phrygia.

SILBODAL, in *Geography*, a town of Sweden, in the province of Warmeland; 35 miles W. of Carlstadt.

SILBOJOCK, a town of Sweden, in the Lapmark of Pitea; 12 miles N. of Niarg.

SILBURY HILL, one of the largest barrows or tumuli in England, and probably in the world, is situated on the Marlborough Downs, about six miles west of the town of Marlborough, in Wiltshire. The origin, appropriation, and history of this extraordinary mound of earth, are alike unknown to the topographer and antiquary. In the vicinity of the immense druidical temple at Avebury, (see *AVEBURY*.) it is rationally supposed to have been originally connected with that structure; and as the most remote antiquities of this island, and of the civilized world, have given rise to much fabulous dissertation, and fanciful hypothesis, so the barrow now called Silbury Hill has been referred to various tribes of people, applied to different purposes, and attributed to the most remote origin. Dr. Stukeley was of opinion that its present name is of Saxon derivation, and signifies "the great or marvellous hill;" while others contend that it is either a corruption for Sil-barrow, which they translate "the peaceful grave;" or of Sel-barrow, meaning "the large or elevated barrow." The most common supposition respecting its nature ranks it among the sepulchral class of monuments. Stukeley calls it the tomb of Cunetha, whom he characterizes as a celebrated British king, who resided at *Cunetis* (then supposed to have been Marlborough), and gave his name to that town, and to the river Kennet, or Kunnet. The Rev. Samuel Greathead, in a letter to Mr. Britton, printed in the account of Wiltshire, in the 15th volume of the "Beauties of England and Wales," regards Silbury as the burial-place of Prydain, a later king of the Britons, to whom he ascribes the union of the British tribes under one monarchy, and the construction of Avebury, as a place of assembly for the chiefs and people on great national occasions. Another opinion respecting this tumulus is, that it was the mount on which the Druids lighted up fires, when they wished to give notice to the surrounding country of some intended religious ceremonial. This view of the subject is of course confined to those who consider Avebury as having been a druidical temple; among whom is the Rev. Edward Davies, author of "Celtic Researches," and of "The Mythology and Rites of the British Druids." To these opinions relative to Silbury Hill may be added a third, which may be regarded as equally probable with any of the conjectures above stated. It is, that, like the Tinwald of the Isle of Man, and the Moote-hill of Seone, it was the mount of justice, the eminence from the summit of which the king promulgated the laws enacted in the national assemblies, and on which he and his judges sat to decide all important causes, whether of a civil or criminal nature.

Silbury Hill is situated directly south from Avebury, and nearly in the centre between the extremities of the two avenues, which extended from the temple to the distance of a mile each way. At the base the hill is about 560 feet in diameter, or 1680 feet in circumference; at the top, 105 feet diameter, or 315 feet in circumference; and it rises 170 feet in per-

pendicular height. Stukeley estimates its solid contents at 13,558,809 cubic feet, and highly praised the choice of the ground, and the symmetrical proportions of the structure itself. In digging here in 1723, a human skeleton, with the bit of a bridle, deer's horns, and an iron knife, were discovered, which Dr. Stukeley confidently considered to have belonged to the person for whom he supposed the mount was raised; but the posture of the skeleton near the surface and on a declivity would render such a conclusion extremely improbable, even though it were undoubted that Silbury is of sepulchral origin. Stukeley's *Abury*, folio, 1743. *Beauties of England and Wales*, by J. Britton, F.S.A. 8vo. 1814.

SILCHESTER, a parish in Hampshire, England, at the northern extremity of that county, bordering on Berkshire, contains the site and ruins of an ancient Roman station. It appears also to have been a city of the Belgic Britons anterior to the Roman colonization of Great Britain, and was called *Caerseiont*, or *Segont*, as being the chief city of the Segontiaci. In the seventh Iter. of Antoninus it is named *Vindomim*, and marked xxi miles from *Venta-Belgarum* (Winchester), and xv from *Callevam* (probably Reading.) That this was a Roman station of importance, appears evident from the various roads, or *vix*, branching from it; from the magnitude and construction of the walls, valla, and amphitheatre; and from the numerous coins and other relics that have been found here at different periods. The whole city, or station, was surrounded by a foss, with a vallum on the inside, on which a wall was raised. This was constructed, in the usual Roman manner, with alternate layers, or rows of large flat stones, rubble stones, and cement, also bricks and flints. In one place this wall was twenty-four feet thick, and the foss was above 100 feet across. The exterior form of this station is unlike any other Roman work in England, being an irregular octagon; whereas those of *Camalodunum* (Colchester), *Venta-Belgarum* (Winchester), *Lindum* (Lincoln), *Londinium* (London), and almost all others, were constructed in the shape of a parallelogram, with the corners rounded off. The inclosed area of Silchester is about one mile and a half in circumference, and contains nearly one hundred acres, the whole of which is appropriated to the arable and pasture lands of a farm. In very dry seasons, it is easy to trace the situation and direction of the Roman streets, two of which intersected the town, and communicated with the four entrance gates, on the east, west, north, and south sides of the city. Near the centre of the area have been traced the foundations of a large edifice, supposed to have been the forum. About 150 yards from the north-east corner of the walls, are the banks of an amphitheatre, which appears to have contained five rows, or terraces for spectators. A small church and a farm-house, with its offices, are all that now remain within the ancient walls; and thus present an amazing contrast to the appearance and pursuits of former times. Now the humble and useful husbandman, with the humane Christian pastor, are the chief occupants of this peaceful spot, which, in the third century, was peopled with Roman soldiers, and was often the theatre of remorseless battle, savage sports, and senseless Pagan ceremonies. A particular account of this place will be found in the 6th volume of "The Beauties of England," by J. Britton and E. W. Brayley.

SILCOLU, a town of Hindoostan, in Myfore; 8 miles S.E. of Seringapatam.

SILDA, in *Ancient Geography*, a town of Africa, in Mauritania *Cæsariensis*, according to Ptolemy. The Itinerary of Antonine places this town on the route from *Tozolofida* to *Tingis*, between *Aquæ Daciæ* and *Vospiscanæ*.

**SILDE REVEL**, in *Geography*, a cluster of small islands belonging to Denmark, in the Cattagat; 6 miles S. of Lefloe.

**SILE**, in *Ancient Geography*, a town of Lower Egypt, on the route from Serapium to Pelusa, between Magdolum and Thauhafium, according to the Itinerary of Antonine.

**SILE**, in *Geography*, a river of Italy, which passes by Treviso, and runs into the Adriatic, opposite to the island of Torcello.

**SILE**, in *Rural Economy*, provincially the name of a milk-strainer.

**SILEBY**, in *Geography*, a large and populous village and parish on the eastern bank of the river Soar, in the hundred of East-Goscote, and county of Leicester, England. The lordship contains about 2139 acres, the greater part of which was inclosed, with other contiguous lands, in conformity to an act of parliament passed in 1759. The manor belongs to earl Ferrers. In the parish were formerly two ancient mansions, belonging to the Sherard and the Poelin families. In 1811 the parish contained 240 houses, and 1200 inhabitants, most of whom were employed in agriculture, and frame-work knitting. Here is one free-school, and three other large schools. The church, a handsome stone building, consists of a nave, aisles, a chancel, a porch, and a tower. The revenues of this church were formerly appropriated to the abbey of St. Ebrulph, in Normandy, which was suppressed by king Henry V. Afterwards the living belonged to the priory of St. Mary, in the isle of Axholme, in the county of Lincoln. Nichols's History and Antiquities of the County of Leicester, folio, vol. iii.

**SILEIN**, a town of Hungary; 14 miles E.N.E. of Bolesko.

**SILENCE**, Fr. in *Music*, equivalent to *rest*; which see.

**SILENE**, in *Botany*, a name given by Linnæus to this genus, the chief of the Catchfly tribe, in allusion to the viscid frothy moisture of its stalks, by which flies of the smaller kind are numerously entrapped. This word is probably derived from *σιλινος, siliva*. De Theis deduces it more directly from the drunken god *Silenus*, whose name he supposes to have a similar origin.—Sm. Fl. Brit. 465. Prodr. Fl. Græc. Sibth. v. 1. 290. Ait. Hort. Kew. v. 3. 83. Gært. t. 130. (Silene; Linn. Gen. 226. Schreb. 304. Willd. Sp. Pl. v. 2. 691. Mart. Mill. Dict. v. 4. Pursh 315. Juss. 302. Lamarck Dict. v. 7. 158. Illustr. t. 377. Cucubalus; Linn. Gen. 225. Schreb. 303. Willd. Sp. Pl. v. 2. 684. Mart. Mill. Dict. v. 2. Pursh 315. Juss. 302. Lamarck Dict. v. 2. 219. Illustr. t. 377. f. 2. Viscago; Dill. Elth. 416.)—Class and order, *Dicandria Trigenia*. Nat. Ord. *Caryophyllei*, Linn. *Caryophyllex*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, swelling, five-toothed, permanent. *Cor.* Petals five; claws narrow, the length of the calyx, bordered with a membrane; limb flat, horizontal, obtuse, often divided, and mossily furnished, more or less, with a cloven, erect, tooth-like crest at its base, constituting the crown of the flower. *Stam.* Filaments ten, awl-shaped, five alternate ones inserted into the claws of the petals, and later than the rest; anthers oblong. *Pist.* Germen superior, cylindrical; styles three, simple, longer than the stamens; stigmas twisted contrary to the motion of the sun. *Perisperm.* Capsule cylindrical, ovate, or somewhat globose, covered by the calyx, more or less perfectly three-celled, bursting at the top into six teeth. *Seeds* numerous, kidney-shaped, attached to a central *receptacle*.

Ess. Ch. Calyx of one leaf, swelling. Petals five, with

erect claws. Capsule superior, imperfectly three-celled, bursting at the top. Seeds numerous.

Obf. The crown of the petals, on which Linnæus depended for his character of *Silene*, in contradistinction to *Cucubalus*, being found not only to separate species most closely related, but even to vary in the same species, as Lamarck and many others have noticed; the authors which stand first on our list of references above, have agreed to remove to *Silene* all the Linnæan *Cucubali*, except *C. baccifer*, on which Tournefort originally founded that genus, which has indeed a crown, but is distinguished by having for its fruit a real berry, not a capsule. See *CUCUBALUS*.

*Silene*, thus considered, is a vast genus, of which new species are still from time to time discovered, in the warmer and drier regions of the south of Europe, and north of Africa; countries abounding particularly with this tribe of plants. All the species in general are herbaceous, many of them annual, very few shrubby. Their stems are jointed, branched, leafy, frequently glutinous, for a certain space, below each joint. The calyx and flower-stalks are also, when downy, somewhat viscid. Leaves opposite, simple, entire. Petals red or white, rarely greenish or yellowish; scarcely ever blue. Some of the flowers, especially the greenish ones, are deliciously fragrant at night; and the rest, if they have any scent, are sweetest at that time, like the Pink tribe in general. We shall select sufficient examples of the genus, particularly describing such as are new, or hitherto only mentioned in the Prodr. Fl. Græcæ, as well as all those of British growth.

SECT. 1. *Stem racemose; occasionally somewhat forked.*

*S. anglica*. English Catchfly. Linn. Sp. Pl. 594. Willd. n. 1. Ait. n. 15. Fl. Brit. n. 1. Engl. Bot. t. 1178. Curt. Lond. fasc. 4. t. 30. (Viscago cerastii foliis, vasculis pendulis, anglica; Dill. Elth. 417. t. 309 f. 398.)—Hairy and viscid. Petals notched. Flowers lateral, erect, alternate. Lower fruit spreading or reflexed.—Native of cultivated fields, on a light sandy soil, in England and France, flowering in July. The root is fibrous, small and annual. Stem branched, spreading, weak and brittle, leafy, round, hairy, swelling above each joint, usually about a foot high. Leaves lanceolate, acute, entire, green, somewhat hairy; the lower ones obovate. Flowers solitary, on short stalks, alternate from the bosoms of the upper leaves. Calyx with ten ribs, swelling as the fruit advances. Petals broadly elliptical, cloven, the claw of each crowned with a divided scale; their colour white, occasionally marked with a faint reddish spot.

*S. quinquevulnera*. Variegated Catchfly. Linn. Sp. Pl. 595. Willd. n. 3. Ait. n. 17. Pursh n. 1. Fl. Brit. n. 2. Engl. Bot. t. 86. (Lychnis hirta minor, flore variegato; Tourn. Inst. 337. Dodart Mem. ed. Amsl. 601. t. 23.)—Hairy. Petals roundish, entire. Flowers lateral, alternate, erect, as well as the fruit.—Native of dry or sandy fields in the south of Europe and the Levant. Mr. Hudson found it near Wrotham in Kent; and Mr. Pursh near Charlestown, Carolina, on the sea-coast. We presume this species to have been carried from Europe to America, being a common hardy annual in gardens, where it flowers in June and July. The plant is not viscid like the preceding, though hairy. The petals are remarkable for a brilliant crimson spot in the middle of each. The lowest capsules are sometimes reflexed.

*S. nocturna*. Spiked Night-flowering Catchfly. Linn. Sp. Pl. 595. Willd. n. 6. Ait. n. 18. Pursh n. 6. Sm. Fl. Græc. Sibth. t. 408, unpublished. (Viscago hirta noctiflora, floribus obsolete spicatis; Dill. Elth. 420. t. 310. f. 400. Lychnis sylvestris hirsuta elatior spicata,

## SILENE.

lini colore; Barrel. Ic. t. 1027. f. 1.)—Flowers spiked, alternate, nearly sessile, directed one way. Petals deeply cloven. Leaves spatulate, hairy.—Native of Spain, the south of France, vineyards about Constantinople, and cultivated ground in Greece; also of Virginia; flowering in June and July. An annual, upright, slightly branched species; the leaves which accompany the flowers narrow, and much smaller than the rest. Petals small, pale pink, or white with a green external tinge, minutely crowned. Capsule ovate, stalked. The flowers are said to expand at night only.

*S. pendula*. Pendulous Catchfly. Linn. Sp. Pl. 599. Willd. n. 27. Ait. n. 37. Prodr. Fl. Græc. n. 979. Curt. Mag. t. 114. (*Viscago hirta ficula*, *lychnidis aquaticæ facie*, *supina*; Dill. Elth. 421. t. 312.)—Flowers racemose. Calyx of the fruit pendulous, inflated, with ten rough ribs. Stem decumbent.—Native of Italy, Sicily, Crete, and Cyprus, flowering in the spring. Every bank about Rome is decorated with this elegant plant in the spring. Nothing is better calculated for the decoration of rock-work, or dry parterres, than this hardy annual, whose purplish stems spread in every direction, and are copiously adorned with large pink flowers, with a membranous, violet-ribbed, inflated calyx. The seeds scatter themselves without any trouble.

*S. vespertina*. Pink Evening Catchfly. Retz. Obf. fasc. 3. 31. Willd. n. 24. Ait. n. 35. Curt. Mag. t. 677. Sm. Fl. Græc. Sibth. t. 409, unpublished. (*S. bipartita*; Desfont. Atlant. v. 1. 352. t. 100. *S. ciliata*; Willd. n. 4, excluding the synonym. *Lychnis marina hirsuta purpurea*, *leucoji folio*; Barrel. Ic. t. 1010.)—Petals with two deep rounded lobes, and a sharp cloven crest. Calyx downy. Leaves spatulate. Stems diffuse.—Found on the sea-shores of Sicily, Barbary, Crete, Zante, and Greece, not uncommon. It has been known about twenty years in our gardens, as a hardy annual, flowering in summer. Linnaeus had specimens, but never determined the species. The stems bear numerous spatulate leaves. The flowering branches are naked below, each terminating in a simple cluster of eight or ten handsome bracteated pink flowers, all drooping one way, with a reddish club-shaped calyx. The pubescence, especially of the calyx, is more close and soft than in *S. pendula*, though more long and shaggy in some specimens than others. The stem is very rarely once forked, being usually altogether racemose.

*S. discolor*. Pale Spiked Catchfly. Prodr. Fl. Græc. n. 981. Fl. Græc. t. 410, unpublished.—Petals with two deep narrow segments, and a notched crest. Calyx villous. Leaves obovate. Stem diffuse.—Gathered by Dr. Sibthorp, in the isle of Cyprus. The root is annual, long. Stems spreading, scarcely a span in length, not forked, though mostly once divided, round, leafy, reddish, rough, like the rest of the herbage, with long spreading hairs. Leaves thick and broad, rather more than an inch in length; the lower ones tapering at the base. Flowers six or eight in each spike, erect, on short partial stalks. Calyx rather slender, hardly an inch long, with ten red hairy ribs. Limb of each petal nearly as long as the claw; pale red on the upper side; light green, with darker veins, beneath; crest white, divaricated, double-toothed.

*S. thymifolia*. Thyme-leaved Catchfly. Prodr. Fl. Græc. n. 982. Fl. Græc. t. 411, unpublished.—Petals with two deep narrow segments, and a notched crest. Calyx hairy, glutinous. Stems procumbent, woody, much branched. Found by Dr. Sibthorp on the sandy shores of Caria and the isle of Cyprus. Root perennial. Stems a foot or two in length, widely spreading, repeatedly branched,

copiously jointed, round, hairy, sending up several terminal, ascending, simple, leafy, hairy, and rather viscid, flowering branches, from three to six inches long. Leaves obovate, acute, rough, about half an inch long, with axillary tufts of still smaller ones. Flowers racemose, three or four at the top of each branch, erect, white; the back of the petals greenish. Calyx an inch long, hairy, pale green, with pink dots.

*S. cerasifoides*. Cerasium-leaved Catchfly. Linn. Sp. Pl. 596. Willd. n. 8. Ait. n. 20. Fl. Græc. t. 412, unpublished. (*Viscago ceratii foliis*, *vauculis erectis sessilibus*; Dill. Elth. 416. t. 309. f. 397.)—Hairy. Petals cloven; crest divided, with a pair of teeth at the base. Stem much branched, spreading, somewhat forked. Leaves linear-lanceolate.—Native of the south of Europe, and of Asia Minor. A hardy annual, flowering in summer, about a span high. Leaves narrow, acute, green, very hairy, an inch or inch and half long. Flowers rose-coloured, spiked, not quite sessile. Calyx very hairy, half an inch long, white, with five green ribs. Floral leaves the length of the calyx. Capsule nearly globose, stalked, with five teeth. Seeds rugged, black.

*S. dichotoma*. Forked Long-branched Catchfly. Ehrh. Beitr. v. 7. 143. Pl. Select. n. 65. Willd. n. 23. Fl. Græc. t. 413, unpublished. (*S. trinervis*; Soland. in Ruffell's Aleppo, ed. 2. 252.)—Petals in two deep narrow segments, with scarcely any crown. Stem forked, racemose, villous as well as the leaves.—Native of Hungary and the Levant. Dr. Sibthorp met with it in Crete, and about the Bithynian Olympus. We believe this species was raised, about 25 years ago, in many gardens about London, from seeds sent by the late Mr. Davall, so that it is entitled to a place in the *Hortus Kewensis*. Root biennial, tapering, as thick as a common radish. Stems several, ascending, from one to two feet high, round, shaggy with long spreading hairs, once or twice forked, with an intermediate, nearly sessile, flower, and then extended into long, simple, spiked or racemose branches, each bearing five or six distant white flowers, whose petals are narrow, with only occasional rudiments of a crest. Calyx with ten green ribs. Anthers green. Seeds red-brown. The leaves are chiefly radical, and very numerous, composing a dense, shaggy, hoary, and somewhat glaucous, tuft; each leaf two inches long, and nearly one broad, obovate, bluntly pointed, tapering down into a broad footstalk.

*S. divaricata*. Forked Spreading-branched Catchfly. Sm. Prodr. Fl. Græc. n. 985. Fl. Græc. t. 414, unpublished.—Petals in two deep rounded lobes, with a cloven crest. Stem forked, divaricated, racemose. Leaves all lanceolate, hairy, acute. Discovered by Dr. Sibthorp on the coast of Asia Minor. In size and habit this bears some affinity to the last, but is more leafy, and the leaves are longer, tapering at each end, undulated, of a darker green, rough with shorter hairs, not shaggy. The flowering branches spread at almost right angles. The flowers are white, but with much broader and rounder petals, each petal bearing a rounded cloven crest.

SECT. 2. Stem forked, with panicled branches.

*S. inflata*. Common Bladder Campion or Catchfly. Fl. Brit. n. 5. Prodr. Fl. Græc. n. 986. Ait. n. 1. (*Cucubalus Behen*; Linn. Sp. Pl. 591. Willd. Sp. Pl. v. 2. 684. Engl. Bot. t. 164. Fl. Dan. t. 914. Behen album; Ger. Em. 678.)—Flowers panicled, drooping. Petals cloven half way down, mostly naked. Calyx smooth, reticulated with veins. Stem erect.—Common in dry fields, pastures, and by way-sides throughout Europe, from Norway to Greece, flowering in the middle of summer. Michaux

## SILENE.

chaux noticed it in Canada. The *root* is perennial, long, whitish, branching at the summit. *Stems* erect, a foot and a half or two feet high, branched, round, glaucous. *Leaves* ovato-lanceolate, acute, glaucous, usually very smooth, but occasionally roughish and fringed; the radical ones numerous, crowded, spatulate. *Panicle* forked, bearing numerous white drooping *flowers*. *Calyx* almost globose, membranous, white, elegantly reticulated with green or purplish veins and ribs. Limb of each petal almost as long as its claw, cut half way down into two spreading, oblong, somewhat rounded segments, generally destitute of a crest, but we have sometimes detected the rudiments of one. *Anthems* green, occasionally liable to a disease, by which they become enlarged, teeming with useless purple dust, which stains the petals. The natives of Zante, who call this plant *νεκάρια*, eat the boiled leaves, which are said to partake of the flavour of green peas.

*S. maritima*. Sea Campion or Catchfly. With. 414. Fl. Brit. n. 6. Engl. Bot. t. 957. Willd. n. 29. Ait. n. 23. (S. amœna; Hudf. Angl. 188. Lightf. Scot. 227. Cucubalus Behen β; Linn. Sp. Pl. 591. Fl. Dan. t. 857. Lychnis marina anglicana; Bauh. Hist. v. 3. p. 2. 357. Ger. Em. 469. Lob. Ic. 337.)—Flowers nearly solitary, terminal. Petals cloven about half way down; the segments of their crest entire. *Calyx* smooth, reticulated with veins. Stem decumbent.—Native of the sandy or rocky sea-shores of Norway, Britain, Gothland, &c. as well as of the stony beds of mountain torrents in Wales, flowering in August and September. The appearance of the *leaves* and *flowers*, at first sight, is so like *S. inflata*, that most botanists, for a long time, considered the plant as a mere variety of that species. They are indeed so nearly akin, as to be inseparable with respect to genus, though *inflata* is mostly without a crown to the *flower*, and this is always furnished with one. The *root* of *S. maritima* is creeping, and the *stems* often quite prostrate, hardly a span high, bearing one *flower*, for the most part, rarely two or three, scarcely constituting a *panicle*. The *leaves* are narrower, linear-lanceolate, or slightly spatulate, very smooth and glaucous, minutely toothed at the edges. *Calyx* much like the last. *Capful* shorter, almost globular. *Styles* occasionally varying to four or five.

*S. fimbriata*. Fringed Campion or Catchfly. Sims in Curt. Mag. t. 908. Ait. n. 46.—Flowers paniced, drooping. Petals divided, many-cleft; the segments of their crest cloven. *Calyx* veined, downy. Stem erect.—Native of mount Caucasus, from whence it was sent to Sir Joseph Banks and Mr. Loddiges. A hardy perennial, readily increased by seeds, and flowering all summer long. The whole plant resembles a large roughish variety of *S. inflata*, but the deeply fringed *petals*, and their evident *crest*, at once distinguish it.

*S. fabaria*. Thick-leaved Campion or Catchfly. Prodr. Fl. Græc. n. 987. Fl. Græc. t. 415, unpublished. Ait. n. 2. (Cucubalus fabarius; Linn. Sp. Pl. 591. Willd. Sp. Pl. v. 2. 685. Been album, seu Polemonium faxatile, fabariz folio, siculum; Boec. Mus. 133. t. 92.)—Flowers clustered, crowded, drooping. Petals in two deep, rather narrow, lobes; the segments of their crest notched. Leaves obovate, with a small point.—Native of rocky places near the sea, in Sicily, Asia Minor, Mount Athos, and the isle of Samos. *Root* perennial. *Plant* very glaucous and smooth, twice as tall as the *inflata*, with much thicker and broader *leaves*. The *stem* is once or twice forked, each of its long upright *branches* bearing several remote, short, tufted *clusters* of drooping white *flowers*, with a reticulated, purplish, tumid, angular *calyx*; and *stalks*, with pointed

*bracteas*, all of the same hue. The limb of each *petal* is half the length of its claw, in two narrow-obovate, spreading lobes; the crest deeply divided, with sharply crenate segments. *Germen* red in the lower half, green above. *Capful* nearly globose. The present species is obviously, according to the Linnæan character itself, a *Silene*, and too closely related to the three preceding, and the following, to be separable from any of them, even in a section of a genus.

*S. Behen*. Oriental Bladder Campion or Catchfly. Linn. Sp. Pl. 599. Willd. n. 25. Ait. n. 36. Fl. Græc. t. 416, unpublished. (Vificago vesicaria cretica, parvo flore purpurascente; Dill. Elth. 427. t. 317.)—Flowers in a corymbose panicle, nearly upright. Petals deeply divided, rounded; the segments of their crest notched. *Calyx* reticulated. Leaves obovato-lanceolate.—Native of Crete, Asia Minor, and Greece.—The *root* of this is annual. *Herb* less glaucous than the last, and more approaching in habit to our common *S. inflata*; but the *flowers* are smaller, and essentially different. The limb of each *petal* is but a quarter the length of its claw, pale pink, in two elliptical, or almost orbicular, lobes, with a white crest, of two, quite separate, notched segments. *Germen* elevated on a stalk of its own length, along with the *petals* and *filaments*, within the *calyx*, as is more or less the case with most of this genus.

*S. casia*. Sea-green Campion or Catchfly. Sm. Prodr. Fl. Græc. n. 989. Fl. Græc. t. 417, unpublished. (Lychnis cretica montis Idæ, folio subrotundo cæfio; Tourn. Cor. 24, by the character.)—Flowers in a corymbose panicle, erect. Petals in two deep linear divisions; the segments of their crest entire. Leaves roundish-obovate.—Native of mount Parnassus, and if we are right in Tournefort's synonym, of mount Ida. This delicate smooth species has a very deep perennial *root*, crowned with a dense tuft of numerous, branching, leafy, round, jointed *stems*, nearly a span high, each terminating in one or two naked flowering branches, about a finger's length, bearing a forked *panicle*, of from four to eight pale, but elegant, *flowers*. The *leaves* are full an inch long, and half as broad, of a deep glaucous green, tapering down into short broad *footstalks*, which clasp the stem. *Bracteas* under the partial *flower-stalks* small, ovate, acute. *Calyx* obovate, half an inch long, tipped with pink, and variegated with green and white, but hardly reticulated. *Petals* narrow, cream-coloured; green underneath; their lobes almost close, or parallel, above half the length of the claw. *Styles* and *filaments* rose-coloured, with greenish *anthers*.

*S. levigata*. Smooth-cupped Catchfly. Sm. Prodr. Fl. Græc. n. 990. Fl. Græc. t. 418, unpublished.—Panicle spreading. Petals cloven half way down, narrow, without a crest. Leaves roundish-elliptical. *Calyx* very smooth and even, without veins.—Found by Dr. Sibthorp in lully parts of the isle of Cyprus. The *root* is annual. *Stems* several, from three to eight inches high, leafy below, smooth like every other part of the plant. *Leaves* of a deep glaucous hue; the radical ones obovate, stalked; the rest ovate, less obtuse, and nearly sessile. *Panicles* forked; the partial stalks much longer than the *calyx*, which is ovate, reddish, peculiarly even and polished. *Petals* small; their limb pink, in two oblong, obtuse lobes, separated but half way down, and destitute of any crest. *Styles* very downy, rather short.

*S. rupestris*. White Rock Catchfly. Linn. Sp. Pl. 602. Willd. n. 52. Ait. n. 54. Fl. Dan. t. 4. (Auricula muris alpina glabra; Bauh. Hist. v. 3. 360.)—Panicle spreading. Petals wedge-shaped, emarginate, with a cloven crest. Leaves ovato lanceolate. *Calyx* smooth, cylindrical, with ten ribs.—Native of dry mountainous situations in Nor-

## SILENE.

way, Sweden, Switzerland, and Greece. The *root* is perennial, tufted, bearing several leafy *stems*, four or five inches high, with a somewhat corymbose *panicle*. *Herbage* smooth, green, scarcely at all glaucous. *Leaves* an inch long, acute, varying in length. *Flowers* small, white. *Capsule* splitting from top to bottom into six valves.

*S. chlorafolia*. Armenian Catchfly. (Sm. Plant. ex Herb. Linn. t. 13. Willd. n. 50. Ait. n. 52. Curt. Mag. t. 807. (Lychnis orientalis viscosa, centaurei lutei folio, flore longifimo; Tourn. Cor. 24.)—*Panicle* spreading. *Petals* cloven half way down, with a two-lobed crest. *Leaves* glaucous, elliptical, pointed. *Calyx* nearly cylindrical, very smooth, without veins.—Gathered by Tournefort in Armenia. Said to have been introduced at Kew in 1796, by Mr. John Hunne-mann. A hardy perennial, twelve or eighteen inches high, flowering in August, readily known by the general resemblance of its *foliage* to *Chlora perfoliata*, though the *leaves* are not perfoliate. *Flowers* large, erect, in a wide panicle, without scent, white, turning reddish as they fade. *Calyx* above an inch long, tinged with purple, very smooth, without ribs or veins, its form slender, cylindrical, or slightly club-shaped.

*S. longipetala*. Long-petalled Catchfly. Vent. Jard. de Cels, t. 83. Sm. Prodr. Fl. Græc. Sibth. n. 992. Fl. Græc. t. 419, unpublished.—*Flowers* pendulous. *Petals* in two deep linear segments; with a notched crest, and hairy claw. *Leaves* lanceolate, rough-edged.—Found by Bruguiere and Olivier, in the neighbourhood of Aleppo. Dr. Sibthorp met with the same in the isle of Cyprus. The *root* is annual. *Stem* two feet high, leafy, panicled, spreading, and many-flowered. *Herbage* rather glaucous, smooth, except the edge of the leaves, which is rough to the touch. *Leaves* about three inches long, acute, strongly ribbed; the lower ones elongated and contracted at the base, clasping the stem at the very bottom. *Flowers* green, quite pendulous. *Calyx* obovate, ten-ribbed, smooth, half an inch long. *Claws* of the *petals* hairy below, as well as the *stamens* and *styles*; limb smooth, very long, involute. *Stigmas* club-shaped, red like the *anthers*.

*S. inaperta*. Small Greenish Catchfly. Linn. Sp. Pl. 600. Willd. n. 39. Ait. n. 44. Sm. Fl. Græc. Sibth. t. 420, unpublished. (Viscago lævis, inaperta flore; Dill. Elth. 424. t. 315.)—*Panicle* spreading. *Flowers* erect. *Petals* in two deep narrow segments; with a double awl-shaped crest. *Leaves* linear-lanceolate, smooth.—Native of Madeira. Aiton. Dr. Sibthorp found it on the mountains of Greece. The *root* in his specimens is creeping, and evidently perennial. Dillenius describes it as annual. *Stems* several, near a foot high, clothed in the lower part with numerous smooth green *leaves*, about an inch long; and branching at the top into a *panicle* of a few pale delicate *flowers*, which seem not to have expanded properly in Sherard's garden, whence originated the specific name. In our Greek specimens the *calyx* is slender, rather club-shaped, an inch long, smooth, with ten green ribs. *Petals* widely spreading, greenish-white above, light brown beneath; their crest small, in two simple awl-shaped lobes. *Capsule* ovate, its stalk, within the *calyx*, as long as itself.

*S. juncea*. Rushy Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 994. Fl. Græc. t. 421, unpublished.—*Panicle* elongated. *Flowers* erect. *Petals* in two deep narrow segments; each lobe of their crest three-toothed. *Leaves* spatulate, all over rough.—Gathered by Dr. Sibthorp in Asia Minor. This has a small, white, annual *root*. *Stem* solitary, erect, two or three feet high; leafy and rough below; terminating in a very long, slender, smooth, slightly spreading *panicle*, of numerous *flowers*, which are rather larger than the pre-

ceding, but with a shorter *calyx*. *Petals* white, with brown veins beneath. The *leaves* are crowded at the root, and bottom of the stem, green, an inch and a half long, somewhat pointed; those about the panicle are awl-shaped and smooth.

*S. cretica*. Cretan Catchfly. Linn. Sp. Pl. 601. Willd. n. 42. Ait. n. 47. Sm. Fl. Græc. Sibth. t. 432, unpublished. (Viscago foliis inferioribus bellidis, superioribus tunicæ, calice strictiore, et turgidiorè; Dill. Elth. 422. t. 314. f. 404, 405.)—*Panicle* sparingly branched. *Flowers* erect. *Petals* in two deep divaricated segments; the lobes of their crest acute, entire. Lower leaves obovate, undulated, roughish.—Found by Dr. Sibthorp on rocks near the sea, in Crete and Cyprus, as well as on the coast of Caramania. A hardy annual, springing up spontaneously year after year in Chelsea garden. The *stems* are two or three, from one to two feet high, erect, slender, viscid. *Leaves* green; the lower ones obovate, obtuse and rough; upper linear-lanceolate, acute, smooth. *Flowers* few, small, but not inelegant, crimson, with a smooth, purplish, obovate, ten-ribbed *calyx*. There is an angular tooth to the claw of the *petals*, at each side, below the crest.

*S. conica*. Corn Catchfly. Linn. Sp. Pl. 598. Willd. n. 21. Fl. Brit. n. 8. Engl. Bot. t. 922. Jacq. Austr. t. 253. Sm. Fl. Græc. Sibth. t. 243, unpublished. (Lychnis calculis striatis, secunda Clusii; Ger. Em. 470.)—*Stem* forked. *Petals* cloven half way down; with a rounded cloven crest. *Leaves* soft and downy. *Calyx* of the fruit conical, with thirty ribs.—Native of sandy corn-fields in the south of Europe and the Levant; rare in England, though it still occurs, as in the time of Dillenius, in the sandy parts of Kent, flowering about July. *Root* annual. *Herb* downy and viscid, of a greyish-green. *Stems* solitary or numerous, spreading, various in height, forked and panicled. *Leaves* linear-lanceolate, acute. *Flowers* erect, pale rose-coloured, fragrant, especially at night, with the scent of a honey-suckle. *Calyx* cylindrical, becoming conical as the capsule swells, and membranous, with thirty green ribs, and five long slender teeth. *Petals* nearly obovate, as is also the white crest of each.—The *petals* appear to be sometimes entire, so that we suspect *S. conoides* of Linnæus may be a variety of this, with smoother broader leaves.

*S. noctiflora*. Night-flowering Catchfly. Linn. Sp. Pl. 599. Willd. n. 31. Fl. Brit. n. 9. Engl. Bot. t. 291. (Ocyroides noctiflorum; Camer. Hort. 109. t. 34.)—*Stem* forked. *Petals* rather deeply cloven; with a short blunt crest. *Calyx* with ten angles, connected by transverse ribs; its teeth as long as the tube.—Native of sandy or gravelly fields, in Sweden, Germany, England, Switzerland, Crete, and Asia Minor; not rare in Norfolk and Suffolk, flowering in July. *Root* annual. *Herb* dark green, softly hairy or downy, spreading, of a coarse rank habit. *Leaves* lanceolate, three-ribbed; the lowest obovate. *Flowers* the size of our common *Lychnis dioica*, (their *calyx* and *stalks* very viscid,) unrolling their pale bluish-coloured *petals* in an evening only, when they exhale, in warm weather, a powerful and delicious scent. The strong reticulated ribs of the *calyx* are remarkable.

*S. leucophaea*. White and Brown Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 1000. Fl. Græc. t. 424, unpublished.—*Petals* in two deep rather narrow segments; with a deeply cloven crest. *Calyx* with ten angles. *Leaves* linear-oblong, recurved, glutinous and hairy. Discovered by Dr. Sibthorp, in the isle of Cyprus. A hairy, glutinous, branching, annual species, about a span high. *Leaves* an inch or inch and half long, green, narrow, obtuse, channelled, somewhat

what revolute, recurved. *Flowers* smaller than the last, especially their *calyx*, which is pale, reddish, destitute of transverse ribs. *Petals* cream-coloured above; of a cinnamon brown beneath; their creft in two rounded entire lobes. This is probably a night-scented flower, like the last.

*S. ramossissima*. Bushy Red Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 1001. Fl. Græc. t. 425, unpublished. (*S. sedoides*; Desfont. Atlant. v. 2. 449? Bivon. Cent. 2. 58. Ocymoides, flore rubro, minus, creticum; Bauh. Hilt. v. 3. 352. cap. 59. *Lychnis hirta angustifolia cretica*; Tourn. Inst. 337.)—*Petals* deeply divided; with a four-cleft creff. *Calyx* club-shaped, with ten angles. *Leaves* spatulate, recurved. *Stem* very much branched.—Native of Crete and Sicily, on rocks near the sea. *Root* annual. *Whole herb* hairy and viscid, green with a brown tint, repeatedly branched from the very bottom, spreading, four or five inches high. *Leaves* about an inch long, obtuse, rather fleshy. *Flowers* very abundant, small, on long, red, hairy stalks, from the forks, sides, and summits of the branches, erect. *Calyx* somewhat obovate, hairy, red, with ten ribs. *Petals* rose-coloured; their limb divided nearly to the bottom; their creff white, in four deep awl-shaped segments. *Capsule* erect, cylindrical, opening with three spreading, obtuse, cleft teeth. *Seeds* black. That this is *S. sedoides* of signior Bivona Bernardi, in his second *Centuria Sicularum Plantarum*, we have ascertained by specimens from himself, since the publication of Prodr. Fl. Græc. But there is reason for hesitation respecting the plant of Desfontaines, which is probably Willdenow's n. 36; the former describes it as procumbent, with only two appendages to each petal, and the latter cites *Lychnis cretica maritima minima*, *portulaca sylvestris folio*, Tourn. Cor. 24, a species unknown to us.

Seçt. 3. *Stem* forked, corymbose.

*S. rubella*. Small-red-flowered Catchfly. Linn. Sp. Pl. 600. Willd. n. 38. Ait. n. 43. Sm. Fl. Græc. Sibth. t. 426, unpublished. (*Viscago lusitanica*, flore rubello vix conspicuo; Dill. Elth. 423. t. 314. f. 406.)—Smooth, corymbose. *Calyx* obovate. *Petals* emarginate; with a rounded two-lobed creff. *Upper leaves* ovato-lanceolate. *Capsule* three as long as its partial stalk.—Native of fields and waste ground, in Portugal, Rhodes, and Cyprus, flowering in spring. *Root* annual. *Herb* quite smooth, of a glaucous green. *Stem* a foot or more in height, branched from the bottom, leafy; all the branches erect. *Lower leaves* obovate, recurved, an inch and a half long; upper rather shorter, acute, lanceolate, slightly ovate, recurved at the point. *Flowers* mostly crowded into a level-topped panicle, with one or two below, in the forks of the branches, pale red, erect. *Calyx* scarcely more than half an inch long, ten-ribbed, smooth, pale, with purple teeth. *Petals* of a dull rose-colour, spreading, inversely heart-shaped, but rather oblong; their creff of two oblong, rounded, entire lobes. *Capsule* roundish-ovate, on a short partial stalk.

*S. orchibula*. Orchis-flowered Catchfly. Linn. Suppl. 241. Willd. n. 46. Ait. n. 50. Sm. Fl. Græc. Sibth. t. 427, unpublished. (*S. Atocion*; Jacq. Hort. Vind. v. 3. 19. t. 32. *Lychnis græca*, bellidifolia verna, flore parvo dilute purpurascens; Tourn. Cor. 24.)—Downy, corymbose. *Calyx* cylindrical-club-shaped. *Petals* four-lobed; with a sharp two-lobed creff. *Upper leaves* ovate. *Partial stalk* as long as the capsule.—Native of the Levant, flowering in May. *Annual*, of the size and habit of the last, but the herbage is of a grays-green, and finely hairy or downy, particularly the stem, the upper part of which is also viscid. *Leaves* broader, sometimes smooth in the

disk, though rough-edged. *Flowers* crowded and level-topped. *Calyx* an inch long, downy, often red. *Petals* rose-coloured, four-lobed like the lip of *Orchis militaris*, having two rounded central segments, and two narrower sharp lateral ones. The lobes of their creff are awl-shaped. The creff is not well distinguished in Jacquen's figure from the lateral lobes.

*S. Armeria*. Common, or Lobel's, Catchfly. Linn. Sp. Pl. 601. Willd. n. 46. Fl. Brit. n. 10. Engl. Bot. t. 1398. Fl. Dan. t. 559. (*Muscipula Lobelii*; Ger. Em. 601.)—Smooth, corymbose. *Calyx* cylindrical club-shaped. *Petals* emarginate; with a sharp two-lobed creff. *Upper leaves* heart-shaped. *Partial stalk* as long as the capsule.—Found in fields, and on banks, in various parts of Europe, but a doubtful native of England, though frequently cultivated as a hardy ornamental annual, flowering in summer. Dr. Sibthorp met with this species in Greece, and on mount Athos. In habit it agrees very much with the last, but is smooth, more glaucous, with broader leaves, and the *calyx* is not downy. The *petals* are simply obcordate, without lateral lobes. There is a brown glutinous ring under each joint of the stem, by which flies are caught.

*S. italica*. Italian Naked Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 1006. Fl. Græc. t. 429, unpublished. Ait. n. 6. (*Cucubalus italicus*; Linn. Sp. Pl. 593. Willd. Sp. Pl. v. 2. 686. Jacq. Obl. fasc. 4. 12. t. 97. not 79, as in Hort. Kew. and Willdenow.)—Panicle corymbose, spreading, somewhat three-forked. *Petals* in two deep narrow segments, without a creff. *Leaves* spatulate, rough.—Native of Italy and Greece. Cultivated by Miller. The *root* is biennial. *Herb* green, roughish with short rigid hairs. *Stem* solitary, herbaceous, erect, twelve or eighteen inches high, leafy, somewhat branched above, but chiefly at the base, from whence it sends out several, decumbent, leafy, purplish shoots, three or four inches long. *Lower leaves* stalked, spatulate or obovate; upper lanceolate; all thin and plant, not fleshy. *Panicle* erect, rather slender, divaricated, more or less downy. *Calyx* an inch long, slightly swelling upward, with ten rough reddish ribs. *Petals* quite naked; their limb cleft nearly to the base, narrow, obtuse; white above; veined with purple underneath. *Capsule* ovate, on a long stalk within the calyx.

*S. catholica*. Panieled Naked Catchfly. Ait. n. 10. (*Cucubalus catholicus*; Linn. Sp. Pl. 593. Willd. Sp. Pl. v. 2. 688. Jacq. Hort. Vind. v. 1. 23. t. 59.)—Panicle forked, much branched, widely spreading. *Petals* in two deep narrow segments, without a creff. *Calyx* obovate, smooth. *Leaves* ovato-lanceolate, nearly smooth.—Native of Italy and Sicily. Mentioned in Cupani's Hortus Catholicus, or Garden of the Prince of La Catholica, whence came the specific name; and not, as many suppose, from the plant being a native of Roman Catholic countries. The plant is perennial, of a tall slender habit, green, smooth, or slightly rough, with a large divaricated panicle, of numerous, small, white flowers, whose calyx is one-third of an inch long, often purple, obscurely ribbed. *Stamens* usually longer than the petals. *Capsule* nearly globose, on a long stalk. We are not quite satisfied respecting *Vijago vesterna non viscosa*, *herbacea flore*; Dill. Elth. 425. t. 316, considered by Linnaeus as a variety of this, but it seems to be *S. parvifolia*, Ait. n. 28. Curt. Mag. t. 68.

*S. mollissima*. Velvet Naked Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 1007. Ait. n. 11. (*Cucubalus mollissimus*; Linn. Sp. Pl. 593. Willd. Sp. Pl. v. 2. 688.)—Panicle corymbose, somewhat three-forked. *Petal* rounded, cleft, without a creff. *Stem*, *leaves*, and *calyx* covered with

with soft down.—Native of the sea-coast of Italy. Gathered by Dr. Sibthorp in Asia Minor, between Smyrna and Prusa. We regret that he had not time to have a drawing taken of this rare and curious species, of which there is not, to our knowledge, any figure extant. Rand mentions the plant as cultivated at Chelsea, in 1739, and Linnæus had it at Upsal. The *stem* is branched, somewhat shrubby. Whole *herbage* clothed with velvet-like pubescence. *Leaves* crowded, spatulate, an inch and a half long, acute, slightly revolute. *Panicles* dense, level-topped. *Calyx* club-shaped, ten-ribbed. *Petals* white or reddish; their limb inversely heart-shaped. We find this plant mentioned in Mr. Donn's Cambridge catalogue, as introduced in 1804. If it exists in any garden, a figure ought to be published.

*S. fruticosa*. Shrubby Catchfly. Linn. Sp. Pl. 597. Willd. n. 14. Ait. n. 26. Sm. Fl. Græc. Sibth. t. 428, unpublished. (*Saponaria frutescens, acutis foliis, ex Sicilia; Bocc. Sic. 58. t. 30. Ocyroides fruticosum; Camer. Hort. 109. t. 33, excellent.*)—Panicle corymbose, close, somewhat three-forked. *Calyx* club-shaped, rough. *Petals* cloven; crest of four teeth. *Stem* shrubby. *Leaves* rough-edged.—Native of rocky situations, near the sea, in Sicily and Cyprus. It is supposed, on the authority of Parkinson's *Paradisus* 254. n. 10, to have been cultivated here in his time. The *stem* is woody, half an inch in diameter, with numerous tufted leafy branches, whose erect flowering extremities, about a span long, are more distantly furnished with smaller leaves, and are downy, viscid, and coloured in the upper part, each bearing a dense level-topped *panicle*, of ten or fifteen large *flowers*. *Leaves* recurved, spatulate, pointed, about an inch long, evergreen, smooth, and shining; the edges only being rough with minute, reflexed, rigid hairs. *Calyx* above an inch long, ten-ribbed. Limb of each *petal* of a long, inversely heart-shaped, form; pink above; veined with green beneath; their crest white, of two acute, somewhat notched, principal segments, and two sharp teeth at the base. In the *Prodr. Fl. Græc.* the figure of this plant is, by mistake, referred to *S. paradoxa*, which will be corrected in the *Flora* itself.

SECT. 4. *Stem* panicled, scarcely forked.

*S. rigidula*. Slender Rigid Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 1009. Fl. Græc. t. 430, unpublished.—*Stem* alternately branched, spreading. *Petals* in two deep sharpish lobes; each segment of their crest four-toothed. *Leaves* lanceolate, smooth.—Discovered by Dr. Sibthorp, on mount Hymettus, near Athens. The *root* is annual. *Stem* erect, a foot high, copiously branched from the very bottom, spreading, slender, purplish, viscid, but, like every other part, destitute of pubescence. *Leaves* green, narrow, few and remote, about an inch long; the lowermost longer and broader. *Petals* pale pink, veined with crimson. *Calyx* club-shaped, pale green, with ten red ribs, smooth, not an inch long. *Capsule* ovate, shorter than its stalk. A very pretty species, whose copious and delicate *flowers* would be an acquisition to our gardens.

*S. spinecens*. Thorny-branched Catchfly. Sm. Prodr. Fl. Græc. Sibth. 1010. Fl. Græc. t. 431, unpublished.—*Stem* shrubby, branches opposite, horizontal, becoming thorns. *Petals* deeply divided. *Leaves* spatulate, downy all over.—Found by Dr. Sibthorp in Asia Minor. The *stem* is thick and woody, very densely branched, leafy, downy, remarkable for its numerous, long, divaricated, lateral shoots, which finally harden into spines. The flowering *branches* are erect, a span high, each bearing a racemose, downy *panicle*, of pale-green *flowers*, veined under-

neath with brown, and, to judge by their aspect, doubtless fragrant at night. *Calyx* about an inch long, green, downy. The crest of each *petal* consists of two small, rounded, white lobes. *Capsule* ovate, twice the length of its stalk.

*S. gigantea*. Gigantic Catchfly. Linn. Sp. Pl. 598. Willd. n. 17. Ait. n. 29. Sm. Fl. Græc. Sibth. t. 432. (*Lychnis græca, fedi arborescentis folio et facie; Walth. Hort. 32. t. 11.*)—*Stem* erect, downy, and viscid. *Flowers* tufted. *Leaves* spatulate, villous. *Petals* in two rounded lobes. *Capsule* nearly globular.—Native of Crete and the islands of the Archipelago; Linnæus by mistake says of Africa. It has long been known in our more curious green-houses, and is esteemed for the sweet nocturnal perfume of its pale green flowers. The *plant*, though a yard high, and of a shrubby aspect, is only biennial. Radical *leaves* two inches long, copious, of a broad spatulate figure, more or less villous, light green, obtuse, with or without a small point. *Stem* straight, viscid; leafy, with several short *branches*, below; slightly branched above, but beset with dense, whorl-like, downy *panicles*, of numerous *flowers*. *Calyx* three-quarters of an inch long, club-shaped, downy. Limb of the *petals* divided more than half way, into two broad rounded lobes, veined beneath with purple; their crest cloven, very short. *Capsule* twice as long as its stalk.

*S. congesta*. Tufted Green Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 1012.—*Stem* somewhat branched. *Panicles* terminal, dense, many-flowered. *Petals* deeply divided, without a crest. *Leaves* spatulate, downy.—Gathered by Dr. Sibthorp in Greece; we believe on hills near Athens. The *root* is woody, evidently perennial, bearing many tufts of copious, spatulate, obtuse, green *leaves*, an inch and a half long, clothed, like the rest of the herbage, with dense, very short, pubescence. *Stems* erect, from nine inches to two feet high, scarcely leafy, bearing a few alternate branches, somewhat viscid at the top, where each terminates in a dense tufted *panicle* of greenish *flowers*, whose *calyx* is half an inch long, obovate, or club-shaped, and whose *petals* are cloven into two rounded lobes, without any crest. This species, of which we have no figure, is in some points allied to the last, but more akin, on the whole, to the following.

*S. viridiflora*. Panicled Green Catchfly. Linn. Sp. Pl. 597. Willd. n. 19. Ait. n. 31. (*Lychnis ocymastri folio, flore viridi; Herm. Parad. 199, with a plate.*)—*Stem* branched. *Panicles* elongated, loose, drooping, many-flowered. *Petals* divided half way; their crest of two linear lobes. *Leaves* elliptic-lanceolate, acute, downy.—Native of Portugal and Spain. The *root* is said, in Hort. Kew. to be biennial, though Hermann calls it perennial. *Stem* one and a half or two feet high, ending in a long loose *panicle* of drooping green *flowers*. *Leaves* two or three inches long, rough, like the rest of the herbage, with extremely minute tubercles, and more or less of short hoary hairs. *Flowers* like the last, but somewhat larger, and furnished with a crown, of which we can perceive no traces in *S. congesta*.

*S. nutans*. Nottingham Catchfly. Linn. Sp. Pl. 596. Willd. n. 11. Fl. Brit. n. 3. Engl. Bot. t. 465. Fl. Dan. t. 242. (*Lychnis fylvestris alba nona Clusii; Ger. Em. 470.*)—*Flower-stalks* panicled, drooping one way. *Petals* in two deep linear segments; their crest of two acute lobes. *Leaves* lanceolate, downy.—Native of dry limestone pastures or rocks, in various parts of Europe, flowering in June and July. It was first, in this kingdom, observed at Nottingham castle, but grows also at Dover, and

## SILENE.

various other places. The *root* is perennial, rather woody. *Stems* several, herbaceous, erect, a foot or more in height, downy; leafy below; racemose, in the first instance, above, the flower-branches shortish, turned to one side, downy and viscid, panicled, or imperfectly forked, each of three or four drooping white *flowers*, which expand in an evening. *Calyx* obovate, near three-quarters of an inch long, ten-ribbed, slightly downy. The lowest *leaves* are spatulate, on long stalks.

*S. paradoxa*. Soap-wort Catchfly. Linn. Sp. Pl. 1673. Willd. n. 13. Jacq. Hort. Vind. v. 3. 45. t. 84. (*Lychnis viscosa peregrina noctiflora odorata*; Zanon. It. 126. t. 50.)—Panicle racemose. Petals inversely heart-shaped; their crest of two acute lobes. Calyx downy. Leaves obovato-lanceolate, smooth.—Native of the south of Europe. Miller cultivated it for the Dover Catchfly, so that it requires a place in the *Hortus Kewensis*, though erroneously admitted into *Fl. Brit.* 467, as is explained at 1397 of the same work. What the older botanists found at Dover, and which may be seen in Petiver's and Buddle's collections in the British Museum, is still an undetermined plant. We greatly suspect, after all the confusion that has attended it, that this Dover Catchfly may be, as Mr. Hudson made it, the true *Cucubalus viscosus* of Linnæus, (see our next species but one,) a Swedish *Silene*, for which Tournefort's *Lychnis orientalis maxima, buglossi folio undulato*, figured in his *Voyage*, v. 2. 148, is erroneously quoted. Botanists of late have found nothing at Dover but *Silene nutans*, varying in size and hairiness. The true *S. paradoxa* is a nearly smooth plant, not very unlike *Saponaria officinalis* in flowers, but more slender in habit. The lower *leaves* are inclining to spatulate; the upper are linear-lanceolate. *Calyx* above an inch long, downy. *Petals* large, pale red.

*S. longiflora*. Long-smooth-flowered Catchfly. Ehrh. Beitr. v. 7. 144. Pl. Select. n. 75. Willd. n. 16. Ait. n. 27. "Waldst. et Kitaib. Hung. v. 1. t. 8." (*S. juncea*; Roth Catal. v. 1. 54. *Lychnis prelongis foliis et calyce*; Barrel. Ic. 63. t. 382.)—Panicle slender, racemose. Petals in two deep, rounded, divaricated segments; their crest of two acute lobes. Leaves linear-lanceolate, smooth, as well as the slightly ribbed calyx.—Barclier says this plant grows in dry stony situations in Tuscany. There can be no doubt as to his synonym, though entirely overlooked by the German writers, who mention Hungary as the country of their plant. This is a tall, slender, elegant, perennial species, quite smooth, with a purple tinge on the *stem* and *calyx*. The latter is above an inch long, slender, nearly cylindrical, with ten obsolete ribs; its surface even and polished, without any pubescence. Claws of the *petals* longer than the calyx; their limb white, tinged externally with red. *Leaves* three or four inches long, half an inch broad, slightly glaucous; the radical ones numerous, on long stalks. This species bears a considerable affinity to *S. paradoxa*, but the long racemose *panicle*, and smooth even *calyx*, afford clear marks of distinction.

*S. viscosa*. Clammy Hairy Catchfly. Ait. n. 3. (*Cucubalus viscosus*; Linn. Sp. Pl. 592. Fl. Succ. ed. 2. 143. Willd. Sp. Pl. v. 2. 685. *Lychnis montana viscosa noctiflora hirtula latifolia alba, floribus absque appendicibus*; Till. Pif. 105?)—Panicle simply racemose, hairy. Flowers opposite, longer than their stalks, drooping every way, without a crest. Stem simple, leafy. Lower leaves lanceolate, even, nearly smooth; upper downy, viscid; dilated and reflexed at the base.—Native of Scania and Finland, where it was gathered by Linnæus; and perhaps of Tuscany; as well as of our hills at Dover; see the last species but one. The Finland specimen, in the Linnæan herbarium,

is a foot high, with a rather stout, round, unbranched *stem*, leafy throughout, moist downy and viscid in the upper part. Linnæus says the *root* is biennial. The three or four pair of lower *leaves* are two or three inches long, pointed, quite even and entire at the margin, nearly smooth, half or three-quarters of an inch wide; as many pair above them are gradually shorter, taper-pointed, even, scarcely wavy, both their surfaces viscid and densely downy, their base greatly dilated, ovate, or almost heart-shaped, clasping the stem. The solitary simple *panicle*, or rather *style*, about five inches long, consists of eight or ten pair of opposite solitary *flowers*, on short simple *stalks*, accompanied by small heart-shaped *bractæas*, altogether very hairy, and apparently viscid, as Linnæus describes them. He says the *flowers* are white, fragrant at night, and do not turn to one side, but drop in all directions. *Calyx* hardly an inch long, cylindrical, hairy, pale, with ten green ribs. *Petals* in two rather deep, somewhat rounded, segments, without a crest. *Capsule* ovate, on a shortish stalk. We do not understand why Linnæus describes the *stalks* as three-flowered. We have no means of knowing whether this plant was cultivated by Miller in 1739; but by his having sent *S. paradoxa* to Linnæus for the Dover Catchfly, it is most probable that neither our *viscosa*, nor Tournefort's species next described, was ever in the English gardens.

*S. buglossifolia*. Bugloss-leaved Catchfly. (*Lychnis orientalis maxima, buglossi folio undulato*; Tourn. Cor. 23. Voy. v. 2. 148, with a figure.)—Panicle simply racemose, hairy. Flowers opposite, much longer than their stalks, erect, without a crest. Stem simple, leafy. Leaves undulated, hairy; the upper ones lanceolate.—Gathered by Tournefort at the foot of mount Ararat, flowering in the middle of August. By his description the *root* should seem perennial, as being divided at the crown into several parts. *Stems* several, a yard high, straight, firm, hollow, leafy, hairy and clammy, four lines in diameter. Lower *leaves* about five inches long, and one broad, ovato-lanceolate, acute, wavy and crisped at the edges, hairy, with a strong mid-rib and many veins; upper gradually smaller and narrower; the *bractæas* linear-lanceolate, mostly equal in length to the *calyx*, which is cylindrical, an inch long. *Petals* white, cut half way down, or more, into two rounded lobes, and apparently destitute of a crest; but Tournefort leaves that important circumstance unnoticed, while he minutely describes the green *germen*, and white *styles*. His plant, though referred by all authors to the preceding, is unquestionably distinct. We have compared specimens.

*S. amoena*. Tartarian Catchfly. Linn. Sp. Pl. 596, excluding all the synonyms, except Hort. Upl. 114. n. 11. Willd. n. 12. Ait. n. 25. (*S. procumbens*; Murray Comm. Gotting. v. 7. 81. t. 2?)—Panicle turned one way; the branches somewhat forked, hairy. *Petals* cloven half way down; their crests converging. Stem decumbent, alternately branched. Leaves lanceolate, nearly smooth.—Native of Tartary and Siberia. We doubt whether this species has ever been cultivated in England, the plant of Mr. Blackburne's catalogue, in 1779, having doubtless been our *S. maritima*, then universally taken for *amoena*. The latter is a spreading, branching, leafy, perennial species, with green *leaves*, an inch or two long, of which the upper ones are minutely downy. The *panicle* is two or three inches long, dense, with leafy lanceolate *bractæas*. *Calyx* pale green, with ten purplish ribs, obovate, finely hairy, rather more than half an inch long. *Petals* white.

*S. regia*. Splendid Catchfly. Sims in Curt. Mag. t. 1724.—Panicle erect, downy and viscid. *Petal* lanceolate, undivided, their crest of two acute lobes. *Calyx* angular, downy.

## SILENE.

downy. Leaves ovato-lanceolate.—Found by Mr. Nuttall, growing wild, in great abundance, in the neighbourhood of St. Louis, on the Mississippi, North America, from whence seeds were communicated to A. B. Lambert, esq. who raised this fine plant in his garden at Boyton, Wilts. The *stem* is two or three feet high, somewhat angular. *Herbage* green, finely downy and viscid; at least in the upper part. *Panicle* racemose, partly forked, composed of about a dozen large *flowers*, conspicuous for the vivid scarlet of their long lanceolate *petals*, *stamens*, and *styles*. The *calyx* is above an inch in length, angular, ten-ribbed, slightly swelling upwards. The *petals* are said to be sometimes emarginate. We guess at their *erect* from the figure cited, which is not sufficiently explicit on this important point.

*S. Otites*. Spanish Catchfly. Fl. Brit. n. 7. Ait. n. 12. Prodr. Fl. Græc. n. 1014. (Cucubalus Otites; Linn. Sp. Pl. 594. Willd. Sp. Pl. v. 2. 688. Engl. Bot. t. 85. Fl. Dan. t. 518. Sefamoides salamanticum magnum; Ger. Em. 493.)—Panicle erect, much branched, tufted. Flowers dioecious. Petals linear, undivided, without a crest. Leaves spatulate, rough.—Native of dry gravelly open pastures throughout Europe, flowering in July and August. In England it chiefly occurs in the elevated champaign country of Cambridgeshire, Suffolk, and some parts of Norfolk, where its green panicles may easily be confounded with those of the accompanying grasses. The *root* is woody and perennial. *Stems* erect, two feet high, slightly leafy, very viscid in the middle part of their upper joints. *Leaves* copious about the root, about an inch in length, on very long stalks; in British specimens they are spatulate, clothed with minute curved pubescence; in Greek ones obovate, with longer hairs. The whole plant indeed varies greatly as to luxuriance, but we cannot discern a specific difference. *Flowers* small, with narrow pale yellow *petals*, and a purplish *calyx*. The *stamens* are usually imperfect, or obliterated, in all the flowers of one root, and the *pisils* in those of another; but occasionally both are perfect in the same. *Capful* sessile, hardly bigger than a grain of wheat, splitting into six teeth.

*S. linifolia*. Flax-leaved Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 1015. Fl. Græc. t. 433, unpublished.—Stems panicle at the top. Flowers erect. Petals in two deep rounded lobes; their crest two-lobed, blunt. Leaves linear-lanceolate, rough.—Found by Dr. Sibthorp on mount Parnassus. The *root* is perennial, thick, woody, yellowish within, much divided at the summit. *Stems* numerous, about a foot high, erect, close, leafy, roughish, quite simple, except in the flowering part, very viscid between several of the upper joints. *Leaves* numerous, narrow, acute, above an inch long, minutely rough, of a glaucous green. *Flowers* erect, in close, irregular, slender panicles. *Calyx* green, smooth, not quite an inch in length, ten-ribbed. Limb of the *petals* flesh-coloured above; greenish, with purple veins, beneath. *Capful* on a stalk as long as itself. These *flowers*, and those of the following, are probably fragrant at night.

*S. staticifolia*. Thrift-leaved Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 1016. Fl. Græc. t. 434, unpublished.—Panicle racemose, simple, close. Flowers erect. Petals in two deep rounded lobes; their crest two-lobed, blunt. Leaves linear-spatulate, acute, very smooth. *Capful* shorter than its stalk.—Gathered by Dr. Sibthorp in Greece.—The *root* appears to be perennial, and somewhat creeping. *Stem* solitary, a foot high, slightly leafy, smooth, like every other part of the plant; the middle of its upper joint, below the inflorescence, viscid. Radical *leaves* numerous, stalked, narrow, glaucous, two inches long, including the stalks. *Flowers* few. *Calyx* club-shaped, an inch and a quarter

long, smooth, with ten purple ribs. Limb of the *petals* inflexed; white above; cinnamon-coloured beneath. The *stalk* supporting all the parts of the flower, within the *calyx*, is remarkable for its length, which nearly equals the *petals*, and exceeds the ripe *capful*.

Seçt. 5. *Stems* single-flowered.

*S. auriculata*. Auricled Mountain Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 1017. Fl. Græc. t. 435, unpublished.—Stems single-flowered. Leaves lanceolate, fringed. *Calyx* bell-shaped, downy. Petals cloven, auricled on each side at the base.—Gathered by Dr. Sibthorp, on the precipices of mount Delphi, in Negropont. The perennial *root* runs deep into the earth, and is crowned by numerous, dense, rose-like tufts, of bright green, ovato-lanceolate, sharp-pointed *leaves*, an inch long; smooth above; their cartilaginous edges fringed with white hairs. *Stems* solitary, erect, simple, downy and viscid, a finger's length, bearing two or three distant pairs of smaller leaves. *Flowers* erect, the size of *S. maritima*. *Calyx* swelling upwards; its veins and segments purplish. Limb of the *petals* deflexed, in two rather deep, oblong, rounded segments, furnished at the base with two very peculiar lateral appendages; their crest of two spreading lobes; their upper side white, tipped with pale purple; the under reticulated with purple veins. *Capful* ovate, nearly thrice the length of its stalk.

*S. falcata*. Sickle-leaved Mountain Catchfly. Sm. Prodr. Fl. Græc. Sibth. n. 1018. Fl. Græc. t. 436, unpublished.—Stems single-flowered. Leaves awl-shaped, curved, hairy. *Calyx* club-shaped. Petals cloven; their claws wedge-shaped.—Gathered by Dr. Sibthorp, on the summit of the Bithynian Olympus. An elegant and remarkable species. The long perennial *root* resembles the last, except in being of a whiter colour. *Stems* very short, tufted, decumbent. *Leaves* crowded, sickle-shaped, about an inch long, rigid, rough with viscid hairs, three-ribbed, permanent, turning white with age. *Stems* ascending, a finger's length, purplish, hairy and viscid, slightly leafy. *Flowers* erect, cream-coloured, with a slender, rough, blood-red *calyx*, above an inch long. The *stalk*, bearing the parts of the flower within, is nearly equal to the *calyx* itself, and much longer than the ripe *capful*. *Petals* with broad claws, dilated upward, and a crest of two bluntish lobes. *Germen* brownish below, with two crimson bands; green above.

*S. Pumilio*. Dwarf Mountain Catchfly or Campion. Wulf. in Jacq. Coll. v. 2. 126. t. 10. Jacq. Austr. append. 26. t. 2. Willd. n. 55. (Cucubalus Pumilio; Linn. Mant. 71. Caryophyllus sylvestris octavus; Clus. Hist. v. 1. 285. C. montanus Clusii; Ger. Em. 593. Betonica coronaria; Bauh. Hist. v. 3. 337.)—Stems single-flowered. Radical leaves linear-lanceolate, smooth. *Calyx* nearly cylindrical, hairy. Petals undivided; their crest bristle-shaped.—Native of the mountains of Carinthia, Moravia, and Italy, in a micaceous soil. A very handsome species. The *root* is perennial, crowned with dense tufts of grassy, or thrift-like, rather succulent *leaves*, about an inch long; among which are several, solitary, partly decumbent, simple *stems*, about twice that length, bearing a pair or two of smaller fringed leaves. The *flowers* are very large in proportion, rose-coloured, and, according to Arduino, who sent specimens to Linnæus, very fragrant, though Clusius and Wulfen describe them as without scent. The *calyx* is an inch long, slightly bell-shaped, reddish, densely clothed with soft whitish hairs. Limb of the *petals* rounded, wavy, but not lobed; their crest, overlooked by Arduino, of two erect slender crimson teeth, growing pale as the flower fades. *Germen* nearly or quite sessile.

*S. acaulis*. Moss Campion, or Catchfly. Linn. Sp. Pl.

Pl. 603. Willd. n. 56. Fl. Brit. n. 11. Engl. Bot. t. 1081. Lightf. 227. t. 12. f. 1. Fl. Dan. t. 21. Allion. Pedem. v. 2. 83. t. 79. f. 1. (S. exscapa; ibid. t. 79. f. 2. S. elongata; Bellardi Append. ad Fl. Pedem. 23. Cucubalus acaulis; Hudf. 187. Lychnis alpina pumila, folio gramineo; Bauh. Pin. 206. Dill. Elth. 206, with a plate. Caryophyllus Pumilio alpinus; Ger. Em. 593. Ocimoide moscoso alpino; Pon. Bald. 199.)—Stems very short. Leaves linear, smooth; fringed at the base. Stalks solitary, single-flowered, naked. Calyx smooth. Petals slightly emarginate; their crest minute, cloven.—Native of the highest mountains of Lapland, Scotland, Wales, Austria, Switzerland, France, and Italy, flowering in June and July. The perennial roots bear numerous, dense, moss-like tufts, of short leafy stems, so that the name *acaulis* is not strictly correct, when applied to this and some other alpine plants. Linnæus was doubtless aware of this, and used such an expression merely to contrast the plants in question with other evidently caulescent species of their own genus. The leaves are bright green, crowded, spreading, measuring from half an inch to an inch. Flower-stalks solitary, simple, slender, naked, smooth, very various in length, whence Allion and Bellardi have exalted some trifling varieties to the rank of species. Flowers pink, with a violet calyx, much smaller than in the preceding, but very elegant. The crest is sometimes so small as to be easily overlooked. Capsule ovate, nearly sessile in its calyx.

We are persuaded that the capsule of this whole genus has properly six valves, or teeth, and that five are never justly attributed to it. We have not indeed had an opportunity of investigating every species, and even the accurate delineator of the *Flora Græca* having most generally exhibited only five of these parts, we cannot but hesitate, though on examining many specimens from which he made his drawings, we find six. A similar inaccuracy has crept into the history of the neighbouring genus *Arenaria*, upon which we may take some other opportunity of commenting.

SILENE, in *Gardening*, contains plants of the hardy herbaceous, and of the annual and perennial kinds, of which the species cultivated are, the common or Lobel's catchfly (*S. armeria*); the variegated catchfly (*S. quinquevulnera*); the pendulous catchfly (*S. pendula*); the Spanish catchfly (*S. muscipula*); the green-flowered catchfly (*S. viridiflora*); the Nottingham catchfly (*S. nutans*); and the shrubby catchfly (*S. fruticosa*).

In the first sort there are varieties with a bright purple flower, with a pale red, and with a white flower.

*Method of Culture.*—The annual and biennial sorts may be raised by seeds, which should be sown in the spring or autumn seasons, where the plants are to grow; but the latter is the better time. Some sow at both seasons, which may be a good practice. The seed should be put in in patches in the borders, clumps, &c. When the plants are up, they should be thinned to two or three plants in each clump, and be kept clean from weeds. With the biennial sorts it is sometimes the practice to sow them in beds; and when the plants are up, to remove them into nursery-rows till the autumn, when they are planted out in the borders, &c.

And the perennial sorts may likewise be increased from seeds, in the same manner; but the usual way is by slips of the heads, and parting the roots, planting them out in shady places, in the spring or early summer months. The shrubby sort may be increased by slips and cuttings of the branches or shoots, which should be planted out in similar situations, in the spring and summer seasons.

They all afford ornament and variety in the clumps and borders of pleasure-grounds.

SILENI, in *Ancient Geography*, a people of India, placed by Pliny in the vicinity of the river Indus.

SILENT, in *Antiquity*, a sort of heathen deities, the same with satyrs, which were called *Sileni* when they came to be advanced in age.

Yet was there one principal Silenus, elder than any of the rest. Diod. Siculus says, he was the master or tutor of Bacchus, whom he disciplined nobly, and followed him to the wars. He quotes an ancient poet, named Thymætas, who relates, that the Sileni assisted Bacchus in the war he waged against the Titans; adding, that the first Silenus reigned in an island made by the river Triton, in Lybia.

He is represented as having a long tail hanging behind, which is likewise an attribute of all his posterity. The poets always mount him on an ass, always drunk, and hardly able to support himself; “titubantem annisque meroque,” as Ovid (*Met.* l. v.) speaks. Upon all the antiques that represent him, he has the air of a drunken man dozing over his wine; and when Virgil, in one of his *Eclogues*, describes him, it is like a man gorged with wine as usual:

“Inflatum hesterno venas ut semper facelo.”

Ancient authors, however, who are very worthy of credit, express more favourable sentiments of him. Silenus, according to their account, was a profound philosopher, whose wisdom was equal to his knowledge; and the drunkenness so often mentioned was merely mystical, signifying that he was profoundly immersed in speculation. Cicero, Plutarch, and many others, had formed the same idea of Silenus, and always regarded him as a very ingenious man, and a great philosopher. Accordingly Virgil, in his second *eclogue*, puts into his mouth the principles of the Epicurean philosophy, about the formation of the world, and the beings that compose it:

“Namque canebat uti,” &c.

Midas, having heard of the extraordinary talents of Silenus, wished for an opportunity of conversing with him. Silenus, who rambled about the country upon his ass, frequently reposed near a fountain, which Midas supplied with wine; and here Midas found him, and treated him with great respect. In consequence of this intercourse, Midas availed himself of the counsels of Silenus, in founding his laws and religious ceremonies. See MIDAS.

A passage in Diogenes Laertius is said to explain the fable of Silenus's riding on an ass; for in comparing Aristotle to Silenus, he says, the first was always on horseback, and the second rode upon an ass: the meaning of which is, that he made only show, but sure, advances in philosophy; whereas the other moved at a quick pace, and now and then made a trip. The fable of the ass's ears, according to Tertullian (*l. ii. de Anima*), informs us, that he was endued with great intelligence. Vossius (*de Idol. l. n.*) explains that of the fountain of wine, by saying that it signified only the desire that Midas had to get Silenus into his possession, who, according to him, was king of Caria, and actually became a great friend to Silenus. He is represented as distinguished for his skill in music. He is said, not only to have invented musical instruments, but to have had the courage, like Marfyas, to challenge even Apollo himself to a trial of skill. Herodotus, speaking of Marfyas, calls him Silenus, *l. vii. c. 26*.

Nomus makes Silenus a son of Tellus; and gives him

three sons, Astræus, Maron, and Lenæus. Servius, on Virgil's Eclogue, makes Silenus the son of Mercury; others, the son of Pan and a nymph; others will have him born of the drops of the blood of Cælus, the father of Saturn.

Ælian (Var. Hist. l. iii. c. 12.) alleges that Silenus was born of a nymph, and that though he was not of the number of the gods, he was, however, of a nature superior to that of man. Silenus is said to have been born at Malea, or at least brought up there, according to the testimony of Pindar, who thus speaks: "Silenus, that incomparable dancer, when a citizen of Malea, the happy spouse of fair Nais had the good fortune to educate." Lucian describes Silenus as of a middle size, fat and plump; and thus he is represented upon medals, and other monuments now remaining.

Bochart, in his "Canaan," will have Silenus to take his name from שִׁילֹן, or שִׁילֹן, *Silo*, the name of the Messiah, whence שִׁילֹן, *Silan*. He also adds, that all that is attributed to this imaginary deity is taken from what the prophets have foretold of Jesus Christ. Thus, whereas it is said, the Messiah shall be the instructor of the people; Silenus is made the preceptor of Bacchus. Because it was said, that our Saviour should bind his ass to the vine, and his colt to the young vine; Silenus is made to ride on an ass. Because our Saviour washed his garments in blood, as those that trod the wine-press; Silenus was made to preside over those who pressed the vintage. Because it is added, his eyes were red by reason of wine; Silenus was made always fuddled. Bochart, however, advances all this with a great deal of distrust, as he has reason, it having no warrant. He adds, that the devil invented the fable of Silenus, to turn the myteries of our religion into ridicule. But the sense which he has given to the words, *rubent oculi ex vino, & dentes ejus ex lacte albescent*, is very forced and unnatural; as if the words signified any thing more, in the propriety of the Hebrew tongue, than, his eyes are redder than wine, his teeth whiter than milk. We may add, that nobody, before Bochart, neither Christian nor idolator, ever saw any thing of Jesus Christ in the fable of Silenus.

Silenus was worshipped after his death as a demigod, and received the honours due to heroes, independently even of Bacchus. Thus Pausanias speaks (in Eliac.), who, mentioning the temple which Silenus had in Elis, expresses himself in these words: "There you will likewise see a temple of Silenus, but a temple which is appropriated and peculiar to himself, while Bacchus has no share in the honour of it."

SILENTIARY, SILENTIARIUS, an officer among the ancient Roman slaves; being, according to some authors, a slave placed over the rest, to prevent any noise and uproar, and to keep them silent.

Seneca, in his Epistles, mentioning the great care taken to keep the slaves mute, has given occasion to Lipsius, Pompa, and some others, to suppose, that the silentiary was established in his time: but others, as Pignorius, think no such conclusion can be drawn from Seneca's words; nor any thing, but that they were, even then, very severe in preventing any noise among the slaves. As to the name and office of the silentiary, it was not established till about the time of Salvian, who is the first author that mentions it.

There were also silentiarii established in the emperor's court, called *quietis ministri*, and *silentiarii palatii*; and honoured with the farther titles of *clarissimi*, *speciabiles*, *devotissimi*, and in Greek *θαυμασιωτατοι*, *q. d. most admirable*.

There were a great number of these; but only thirty ordinarily officiated, who were divided into three bands,

each of which had its decurio. The council of Chalcedon call the body of silentiaries, *schola devotissimorum silentiariorum*.

SILER, in Botany, a Latin name in Virgil, supposed to belong to some slender kind of willow, or osier. It is used vaguely, by the earlier botanists, for different umbelliferous plants, and retained by Gærtner, after Rivinus, for *Laserpitium trilobum* and *aquilegifolium*, which those writers place in a genus by themselves. Linnæus uses the above word, as the specific appellation of another LASERPITIUM. See that article.

SILESIA, *Duchy of*, in Geography, a country of Europe, bounded on the N. by the marquisate of Brandenburg, on the E. by the duchy of Warlaw and Austrian Poland, on the S. by Hungary, from which it is separated by a chain of mountains, and a wilderness or thicket, about four miles broad, and on the W. by Moravia, Lusatia, and Bohemia. To the W. and S. Silesia is environed by a chain of hills, being with respect to extent and height some of the most remarkable in all Europe. (See SUDETIC Chain.) For other mountains of Silesia, and their productions, see PRUSSIA. In the mountains of this province, and in that part of it that lies towards Moravia and Hungary, the winter is earlier and of longer continuance, and much more severe, than in the more level territories. During those months, in which at the foot of the Riesengebirge and the Gefenk every thing is covered with ice and snow, the trees at Breslau are in full verdure even in winter. The sandy parts of the principality of Glogau, and beyond the Oder, towards Poland, with the mountainous tracts, which are of considerable extent, produce but little, nor is their grain sufficient for the consumption of the inhabitants. But this deficiency is compensated, in favourable seasons, by the fertility of the other and larger part of Silesia, which, besides wheat, rye, barley, and oats, yields likewise maize or Turkey-wheat, spelt, buck-wheat, millet, linseed, pease, and beans. The culinary vegetables about Breslau, Brieg, Neisse, Frankenstein, and Lignitz, are excellent: and the vicinity of Grunberg and Lower Beuthen affords plenty of fine fruits. Those spots that are not fit for tillage afford good pastures, or are covered with wood. Of flax there is abundance, but hemp in less plenty, which is supplied by importation from Hungary and Poland. Hops principally abound near Munsterberg. Madder forms one of the principal articles of export. A yellow dye, called *scharte*, is plentiful; nor is this country deficient in tobacco plantations; but its saffron is of an indifferent quality. The wine of the country is good, more especially after it has been kept for some years in the cellar. In the mountains and Upper Silesia, tar, pitch, and resin, are made from the pine and fir, and the larch-tree produces turpentine. From these resinous trees, and the trunks of the coarser pines, the inhabitants of the mountains make a lamp-black. Terra sigillata is found in many places, and particularly near Strigau; but it is used not as an article of the materia medica, but principally in the manufacture of earthenware. Cattle are reared merely for the plough, and for the necessary supply of milk, butter, and cheese; but the markets are furnished, particularly with oxen, from Poland and Hungary. The most noted markets are those of Brieg, Breslau, and Schweidnitz. Although the studs in this country afford many fine and stout horses, the number is not sufficient: and therefore, besides those that are purchased at Frankfort fair, great numbers are brought hither from Lithuania. The inhabitants of the hilly districts keep goats, and cheese in great quantity is made from their milk. The breed of sheep is considerable and

and lucrative, on account of the excellent quality of their wool. The wild beasts of this country, whose skins are valuable, are lynxes, foxes, weasels, otters, and beavers. The Oder furnishes salmon and sturgeon, skate, lampreys, &c. The other rivers, as well as the lakes and ponds, abound in various kinds of fish, such as pike, carp, trout, mullets, &c. Bees are bred for a supply of wax and honey, but their commodities are not in sufficient quantity to supercede the necessity of importation from Poland. Silk is in a state of increasing cultivation. The principal manufactures of Silesia are those of thread, twine, linen, flax, and damask. The chief exports are madder, mill-stones, thread, yarn, linen, wool, and woollen cloth, together with stuffs and paper. Under the dominion of the king of Prussia the commerce of Silesia has been considerably improved.

The prevalent religion in Silesia, as well as in Prussia, is the Protestant; and the bishoprics here, as well as in Poland, retain their ancient limits, while the power of the prelates is much abridged.

The manners and customs of the inhabitants of this province resemble those of their neighbours the Bohemians; but those of both these races have been so much melted down into that of the Germans, that the peculiar features are minute and unimportant. Silesia has some pretensions to literary fame. The capital of Silesia is Breslau; besides which there are only three towns which contain more than 600 inhabitants, *viz.* Glogau, Hirschberg, and Schweidnitz. For other particulars, see PRUSSIA.

Silesia affords few materials for history. Its ancient inhabitants were the Lygii and Quadi; but about the middle of the sixth century, the Slavi having overrun the country of the latter, a part of it was annexed to Poland, and called "Zlezia." Under the Polish sovereigns, Silesia received the Polish language, manners, and usages, with the Christian religion. After having been a Slavonic province of the Polish dominion, it was seized, in the 14th century, by John of Luxemburg, king of Bohemia (February, 1339), and passed with that sovereignty to the house of Austria. On the death of the emperor Charles VI. in 1740, Frederick II. king of Prussia, laid claim to the principalities of Lignitz, Brieg, and Wohlau; and his claims were so effectually supported by the march of an army into Silesia, that Maria Theresa, daughter and heiress of the emperor Charles VI. and queen of Hungary and Bohemia, by a preliminary treaty at Breslau, which was soon followed by a ratification of the same at the peace of Berlin, did, on behalf of herself, her heirs and successors, of both sexes, for ever cede to the king of Prussia, and his heirs and successors, of both sexes, with entire sovereignty and independency of the crown of Bohemia, the countries of Upper and Lower Silesia, together with the district of Katscher, formerly belonging to Moravia, as also the county of Glatz; reserving, however, to herself the principality of Teschen, with the lordships annexed thereto, the part of the principalities of Troppau and Jagerndorf, beyond the Oppa, the part of the principality of Neisse bordering on Moravia, and a small district belonging to Moravia, with some frontier towns. Silesia was never immediately connected with the empire, having at no time been an imperial fief, nor obtained a seat or vote in the diet. Neither has it been ever subject to the supreme tribunals of the empire, so that here the imperial laws are of no force. This event happened in 1742. The king of Prussia having obtained the greater part of this country with entire sovereignty, and absolutely independent of the crown of Bohemia, governs it accordingly, as a state absolutely free and divested of the least connection with the empire: but in the year 1751, the empire becoming a guarantee to his Prussian

majesty for the secure possession of the duchy of Silesia, a proviso was made for its rights consequential to such an engagement. Ever since the close of the twelfth century, Silesia has been divided into the Upper and Lower, and this division is still in use. Lower Silesia contains thirteen principalities, the names of which are as follow; *viz.* Breslau, Brieg, Glogau, Jauer, Lignitz, Munsterberg, Glatz, Neisse, Oels, Sagan, Schweidnitz, Wohlau, Trachenberg, and Carolath; the free landesherrschafts or lordships of Wartenberg, Miltsch, and Gofchutz; and many minderherrschaften or inferior lordships. To Upper Silesia belong the six principalities of Teschen, Troppau, Jagerndorf, Oppeln, Ratibor, and Bilitz, the free landesherrschafts of Pleß and Beuthen, and certain minderherrschafts. At present under two sovereigns, the capital divisions must necessarily be into that of Prussian and Bohemian. Breslau is the capital of Prussian Silesia. The regency of Bohemian Silesia is erected at Troppau. The whole country is said to contain 180 cities and towns, 4000 villages, and 1,890,000 inhabitants. For other accounts of the population, see PRUSSIA.

SILESIACA TERRA. See TERRA.

SILEX, *Kieselerde*, Germ., in *Mineralogy*, a species of earth which is generally found in a stony state, and from its forming nearly the whole composition of flint, it has acquired the name of sillex, or siliceous earth. It is found in equal or perhaps greater purity in rock-crystal and quartz, and in white sand; and it is probably an earth that most abounds on the globe. Most of the stony combinations of sillex are remarkable for their hardness, and will very readily strike fire with steel. Sillex, when pure, is white, and perfectly void of taste and smell; it is insoluble in water, and incapable of artificial crystallization. For its other properties, see FLINT and SILICA.

SILHET, in *Geography*, a circar of Hindoostan, in the N.E. part of Bengal, bounded on the N. by Bootan, and on the E. by Meekley, and elsewhere by a part of Bengal.—Also, a town of Hindoostan, and capital of a circar, to which it gives name; 106 miles N.E. of Dacca. N. lat. 24° 52'. E. long. 91° 57'.

SILI, in *Botany*, a name given by the old Greeks to a plant called also *seseli*.

SILJAN, in *Geography*, a town of Sweden, in Dalecarlia, on a lake to which it gives name; 25 miles N.W. of Fahlun.

SILICA, in *Ancient Geography*, a town of Africa, in Interior Libya, near the river Bagradus. Ptolemy.

SILICA, in *Mineralogy* and *Chemistry*. In the former it is an earthy substance, existing abundantly in the composition of the globe, and forms a distinct genus of minerals in such as it predominates. In chemistry it was formerly considered as a simple body, under the class of earths. In the present state of chemistry it is regarded as a metal combined with oxygen, and belongs to one of the most extensive class of compounds in chemistry.

The minerals in which it is principally found are rock-crystal, quartz, agates, and flints. The first of these almost wholly consists of silica. In order, however, to obtain it in perfect purity, let the rock-crystal, or quartz, be heated red-hot, and then plunged into cold water. This has the effect of lessening its aggregation. To facilitate its reduction into powder, let one part of this powder be fused in a silver crucible, with three parts of pure potash. The fused mass will be found soluble in pure water. To the clear solution add any acid sufficient to saturate the alkali, but not more. A gelatinous precipitate will be found, which, when well washed, dried, and heated to ignition, in a silver crucible, will be pure silica.

It is a fine white powder, harsh to the touch, and destitute of taste or smell. Its specific gravity is 2.6.

Silica is not acted upon by the air, nor changed by moisture. When strictly pure, no ordinary heat will fuse it. It does however put on appearances of fusion, when heated by the aid of a blowpipe and oxygen gas. It does not combine with oxygen, sulphur, phosphorus, carbon, or azote.

The two fixed alkalies do not affect it in the cold, but when fused with it in a silver crucible they combine, forming compounds, which have all the appearance of glass. Indeed, when the two bodies are in one proportion, they form the purest and most perfect glass. When the alkali is to the silica as three to one, the compound is soluble in water. This solution has been called the *liquor of flints*. Any of the acids are capable of combining with the alkali, and precipitating the silica in a state of purity, as we have before observed in the process for obtaining silica.

If an excess of acid be added to the solution, part of the silica is dissolved. This is more especially the case with the muriatic acid. A very dilute solution of silica in potash, in a vessel covered with paper, was left at rest by professor Seigling for eight years. Crystals of silica were found in the fluid, and the surface had a transparent crust upon it, strong enough to allow the vessel to be inverted without spilling the liquid. Some of the crystals were found to be pure silica, in groups of tetrahedral pyramids. There were also crystals of sulphate and carbonate of potash. The former were so hard as to strike fire with steel.

When fluoric acid is distilled from a glass vessel, or from any other substance containing silica, this acid assumes a complete gaseous form. The moment it is absorbed by water, a proportion of silica is precipitated. In this case, the gas which comes over is a compound of silica and the acid, which may be called fluat of silica. The liquid acid is also found to hold silica in solution. It was from this solution, after standing two years, that Bergman obtained crystals of pure silica. They were of a cubic form, with three angles truncated. They were not so hard as rock-crystal.

The boracic and phosphoric acids have no action upon silica in the cold, but unite with it by fusion, forming transparent vitreous substances.

Silica does not combine with any of the metals, but it combines with many of their oxyds, forming compounds, which are called glasses, enamels, or porcelains, according to their appearance.

With the oxyd of lead it forms the glazing of common pottery; with oxyd of iron, a dark green or black glass.

We have already spoken of its combination with the alkalies which belong to this class of compounds.

When a solution of lime or barytes in water is added to a solution of silicated potash, or liquor of flint, those earths become precipitated, forming a peculiar compound.

A similar combination takes place when a solution of silica in potash is added to a solution of alumine in the same alkali.

Although the fusibility of silica is impracticable at the heat of our hottest furnaces, yet its combination with other earths is fusible, though at a very high temperature. Equal parts of lime and silica fuse into a mass between porcelain and enamel at 150° of Wedgewood. We hence see the use of lime in smelting iron ores which abound with silice.

Silica appears to be the most abundant of the earths, forming the greatest proportion of the primitive rocks, and the basis of the terrestrial globe.

Although it has not been directly proved to be a metallic oxyd, there is the most presumptive reason for thinking it so. From the small action which acids had upon it, compared with the other earths, sir Humphrey Davy at first suspected it to be an earth already combined with an acid, and made some attempts, by the aid of Galvanism, to verify this idea, but without success. He fused silica with iron by the Galvanic battery, and obtained a mass which afforded silica when dissolved by an acid with water. He also heated silica to whiteness, and on bringing potassium in contact, a compound was formed of silica and potash, but a number of black particles were diffused through the mass, which sir Humphrey Davy thought were conductors of electricity. They did not act upon water; but when an acid was added, an effervescence took place. They also burnt in a strong heat, affording a white substance, which had the characters of silica.

Little is known of the proportions in which silica combines with other bodies. Dalton gives its atom as forty-five times heavier than hydrogen: and sir Humphrey Davy states the number for silica at sixty-one, which, reduced to Dalton's standard, would be 30.5. But neither of these is to be depended upon.

SILICEOUS, in *Mineralogy*, denotes composed principally of silice.

SILICEOUS *Schistus*, in *Mineralogy* and *Geology*, the hornstone slate of some geologists; flinty slate of Jameson; a rock of the nature of slate, but containing a great portion of siliceous earth. It frequently occurs in beds in clay-slate, and sometimes forms entire mountains, which are either homogeneous or porphyritic, containing crystals of felspar, and forming porphyritic flinty slate. The colour consists of various shades of grey, but it is sometimes red, approaching the nature and colour of jasper. It is generally traversed by veins of quartz, but rarely, if ever, contains metallic veins. It is extremely hard, and breaks with difficulty; the fragments are sharp-edged, and more or less translucent in minute portions. The Lydian stone, which is used as a test, or touch-stone, for determining the purity of metals, is nearly allied to siliceous schistus. This rock passes, by gradation, into clay-slate; and when the silice predominates, into hornstone or chert.

SILICEOUS *Earth*, in *Agriculture*, such as is constituted of siliceous materials.

SILICEOUS *Marle*, that which is of a sandy or siliceous nature. See MARLE.

SILICERNIUM, among the *Romans*, a funeral supper, which is otherwise called *exequium*.

SILICIATE, in *Mineralogy*, a term lately introduced by professor Berzelius, to denote the combination of silice with other earths or oxyds, in which the silice is supposed to act as an acid. These substances he denominates silicates. As this view of the action of silice tends to throw considerable light on various processes in the mineral kingdom, it is but justice to our own countryman, Mr. Hume, a respectable scientific and practicable chemist in London, to state, that so early as 1805, he had, in Mr. Park's Chemical Catechism, asserted the action of silice as an acidifying principle, and subsequently in the *Philosophical Magazine* for 1808, he distinctly and perspicuously described various processes, both natural and artificial, in which silice performed the part of an acid: this he attributed to the great proportion of oxygen contained in it. As silice is by far the most abundant substance in the composition of the globe, either pure or in combination with the other earths, its peculiar properties, and the part which it performs in the successive changes that take place in the mineral kingdom, are a sub-

ject of much interest both to the geologist and the chemical philosopher. The similarity of its effects with those of oxygen and acids, have been pointed out in a very striking manner by Mr. Hume in the paper before referred to.

There is a remarkable similitude in the effects of oxygen and silicic acid on the metals, particularly in that process called vitrification, which is, in every meaning of the word, a complete saturation and oxydation. By means of silicic acid, all the metals (perhaps without exception), from being the most opaque bodies in the universe, may be rendered quite pellucid, affording an endless variety of the most charming tints. It is chiefly from metallic substances that the most durable colours are obtained, particularly for staining glass, and making artificial gems. The best opaque colours, such as are most suitable for enamel, water, oil, crayon, and all other descriptions of painting, are derived also from the metals combined either with silicic acid or oxygen. Even the precious stones, and the less valuable crystals and pebbles, with an infinite number of mineral productions, seem to derive their beauty and value from the action of silicic acid on the metals. Thus, the opacity of lead is effectually changed by the sand or silicic acid used in the composition of flint-glass, and the compound is rendered not less diaphanous, than when, by means of oxygen, the same metal is dissolved in dilute nitric acids.

The power which silicic acid exercises over potash and soda, and a variety of other substances which enter into the composition of glass, is a striking and well-known instance (says Mr. Hume) of its neutralizing efficacy; for no acid more completely obtunds the acrimony of alkaline bodies, and disarms them of their corrosive character. The effervescence which results when silicic acid and the alkali enter into fusion and form this tasteless compound, is not observable till the materials are on the point of perfect combination; hence, as something is apparently evolved, neither oxygen nor any other aeriform fluid can be supposed to enter; so that the acidifying power (if the term may be applied) which appears to coerce the alkaline matter, is alone due to the sand which is usually employed to form glass. Indeed vitrification seems, in all instances, to be accomplished by silicic acid, or by oxygen, and the glass of lead, of antimony, of phosphorus, borax, or any other body, is due to the one, as much as the glass in common use is to the other of these oxygenating agents.

The power of silicic acid, as an oxydizing, saturating, and neutralizing agent, is by no means confined to rocks, minerals, and the inanimate parts of created matter; but it pervades also, as an essential element, the structure of organized beings, and occupies a distinguished place both in the animal and vegetable economy. "Nothing is more astonishing," says Dr. Smith, "than the secretion of stony earth by plants, a fact which is well ascertained." According to modern experiments, human hair, and probably the hair of all animals whatever, also contains silicic acid as a constituent element.

From numberless phenomena that admit of no other interpretation, it may justly be inferred, says Mr. Hume, that nature possesses means of converting silicic acid into other forms, and of so interweaving it into the constitution of her varied works, that it ceases entirely to appear in its original state. Every thing connected with the progress of animal and vegetable existence, with the inscrutable secrets of the assimilating powers, or with the physiology of all organized matter, shews that transmutation is an operation which we cannot disprove, though we may not be able to trace it through all its steps.

According to Berzelius, silicic acid, or silica, considered as an

acid, possesses the property of giving silicates of many different degrees of saturation. The most general is that in which silicic acid contains the same quantity of oxygen as the base: these he denominates simply *silicates*. The next most general are those in which silicic acid contains three times the oxygen of the base; these he calls *trisilicates*: it not unfrequently contains twice the oxygen of the base; these combinations he calls *bisilicates*. Silicic acid also produces a great number of combinations with excess of base of different degrees, which he denominates *subsilicates*, to which again he applies the appellations *bi*, *tri*; for example, *bialuminous subsilicate*, *trialuminous*, &c. all announcing that the base contains twice or three times the oxygen of the silicic acid.

Silicic acid, like other acids, gives also double silicates, partly with and partly without water of crystallization. We most frequently find, that the bases which have a tendency to produce double salts with other acids, do the same thing here: in the same manner, as in the double silicates, we again find (although with many exceptions) the same proportion between the bases as in the other previously known salts with double bases. Hence, for example, if in common felspar we could exchange silicic acid for sulphur, the combination would be alum without water.

But Nature in her rich stores, says Berzelius, exhibits a number of combinations of silicic acid still more various, for which we have few if any analogous combinations to produce from the experiments in our laboratories. Thus we find silicates with from three to four bases, which all form one common combination, whose pure crystalline structure seems to render it evident that it must be considered as one chemical whole; unless it should hereafter be proved that such bodies belong to the class of crystals that are formed of many different substances lying in juxtaposition, but not chemically combined.

It often happens, also, that these numerous silicates are not of the same degree of saturation, but that one or more of the weaker bases are subsilicates, or silicates, while one or more of the stronger are *bi* or *tri*-silicates. That similar combinations are not formed in our laboratories, arises evidently from the rapid and violent means by which these combinations are effected, which will not admit the action or influence of those weaker affinities which take place in the secret and undisturbed recesses of the mineral kingdom. As it is of importance to ascertain the quantity of oxygen in silicic acid, in order to determine its proportions in the different combinations of silicates, Berzelius, from various experiments made by himself and others, estimates the proportion of oxygen to be 49.64. See SILEX.

SILICULA, in *Botany*, the diminutive of SILIQUA, (see that article,) is a Pouch, or pod of a short, or rounded, figure, along both the edges of whose partition the seeds are inserted; witness the *Draba verna*, or Whitlow-grass, so common on walls in the spring, and the *Thlaspi Bursa-pastoris*, Shepherd's purse. The partition is always really parallel to the valves, though the latter are often so protuberant, as in the *Thlaspi*, that their depth is much greater than the real diameter of the fruit. Hence Linnæus has fallen into an error, first detected by Mr. Brown, in the character of SUBULARIA. See that article.

SILICULOSA, the first of the two orders of the 15th class in the Linnæan system, TETRADYNAMIA, (see that article,) the character of which order consists in the short, or rounded, not oblong, form of the seed-vessel. See SILICULA.

SILIFREY, in *Geography*, a town of Africa, in the kingdom of Barra.

SILLIACON, in *Botany*, a name given by some of the old

old Latin writers to the carob tree, *filiqua dulcis*. The Latins borrowed this name from the Greek *xyloglycon*, *ξύλογλυκόν*, the sweet, or sweet-fruited tree.

Ifidore mispels the word *filicon*, and making it only *filicon*, supposes it to be a barbarous way of spelling the word *filiqua*; but the evident derivation of the genuine word from the Greek, shews his error both as to the word itself, and the origin of it.

SILIN, or ABU AIT, in *Geography*, a town of Egypt; 12 miles S.S.E. of Siut.

SILINDIUM, in *Ancient Geography*, a small town of Asia Minor, in the Troade, near mount Ida.

SI-LING, in *Geography*, a town of China, of the third rank, in Quang-fi; 20 miles S. of Si-long.

SILINO, a small island among the Philippines, near the north coast of Mindanao. N. lat. 9° 2'. E. long. 121° 40'.

SILINUS, in *Ancient Geography*, a river of the Peloponnesus, in the Elide, which watered the territory of the Scillunte, according to Pausanias.

SILIPICA, in *Geography*, a town of South America, in the province of Cordova; 20 miles S. of St. Jago del Estero.

SILIQUA, *σιλική*, among the ancients, the third part of an obolus, or, what comes to the same, the sixth part of a seruple.

SILIQUA *Nabathæa*. See NABATHÆA *Siliqua*.

SILIQUA, in *Botany*, a Pod, is a sort of PERICARP. (See that article.) The *Siliqua* is a solitary seed-vessel, of an elongated form, and dry substance, consisting of two parallel valves, separated by a parallel linear partition, or receptacle, along each of whose edges the seeds are ranged in alternate order. Examples are found in the Cruciform plants, constituting the Linnæan class *Tetradynamia*, such as *Cheiranthus*, the Stock or Wall-flower; as also in *Chelidonium*, the Celandine; and *Bignonia echinata*, Gærtn. t. 52. f. 1. This kind of seed-vessel differs from a LEGUME, (see that article,) in having the seeds inserted along each of its margins.

SILIQUA. See CAROB.

SILICUASTRUM, the appellation of the Judæe-tree in Tournefort and preceding authors, alluding to its partial resemblance to the fruit of the Carob, which was called *Siliqua*, the Pod, by way of eminence. See CERATONIA and CERVIS.

SILICUASTRUM, in *Natural History*, the name given by Mr. Lhuyd, and others, to the bony palates of fishes, when found fossil. See ICHTHYPERIA.

SILICUATICUM, among the Romans, a custom or toll paid for merchandize. This the Greeks called *ceratistmus*.

SILICUOSA, in *Botany*, the second order of the Linnæan 15th class, *Tetradynamia*; which order is characterized by the oblong form of the seed-vessel. See SILIQUA and SILICULA.

SILICUOSÆ, the 39th natural order, among the *fragmenta* of Linnæus, exactly analogous to the CRUCIFERÆ of Jussien. See that article, as well as, hereafter, TETRADYNAMIA.

SILIS, in *Ancient Geography*, a river of Italy, in Venetia, which had its source in mountains called Taurifani.

SILISTENI, in *Geography*, a town of Moldavia; 10 miles S.W. of Huff.

SILISTRIA. See DRISTRA.

SILIVRIA, or KILLEEVER, a large and populous town on the sea of Marmora, once well fortified, and still

in part furrounded by a strong wall. Some of its mosques and minarets are very handsome buildings. The lower part of the town is washed by the sea. Its bay is capable of accommodating a considerable number of vessels, and is so well sheltered by the high land on each side of it, that ships may, in any weather, ride in safety.

SILIUS ITALICUS, CAIUS, in *Biography*, an Italian poet, was born about the year 15 of the Christian era. He has been supposed to have been a native of Italica in Spain; but his not being claimed as a fellow countryman by Martial, who has bestowed upon him the highest praises, renders the supposition improbable. It is certain that he lived chiefly in Italy, in which he possessed several estates. The knowledge of him come down to these times is derived from a letter of Pliny the Younger to Caninius Rufus, announcing his death. From this it appears that he incurred some reproach in the reign of Nero, as having been forward in accusations, and that he was consul at the time of the tyrant's death; that he made a discreet and humane use of the friendship of Vitellius; and that having acquired much honour, from his conduct in the proconsulate of Asia, he thenceforth withdrew from public offices, and maintained the rank of the principal persons of the city without power, and without envy. It appears, likewise, that he passed his time chiefly in literary conversations, and in composing verses, which he sometimes recited in public. He had great taste for elegance, and purchased a number of villas, which, after enjoying for a time, he deserted for new ones. He collected a number of statues, books, and busts, to some of the latter of which he paid a kind of religious veneration. This was particularly the case with respect to that of Virgil, whose birth-day he kept with much more ceremony than his own, and whose tomb was included in one of his villas. He is said also to have possessed a villa that had been Cicero's. In his latter years he retired altogether to his seat in Campania, which he did not quit upon any account; and the general tide of his prosperity did not cease to flow, except in the instance of the death of the younger of his two sons, which was in some degree compensated by the consular dignity of the elder. In his 75th year he was attacked with an incurable ulcer, and he is said to have put an end to his life, by abstaining from food.

The work of Silius, which has come down to the present time, is an epic poem on the second Punic war. In this he scarcely deviates from Livy, in the narration of transactions; but occasionally introduces a machinery, copied from Virgil, of whose style and manner he is an imitator. Pliny says, that "he writes with more diligence than genius." The best editions of this work are those of Drakenborch, 1717; and of Lefebvre de Villebrune, 4 vols. 12mo. 1782.

SILK, SERICUM, a very soft, fine, bright, delicate thread; the work of an insect, called *bombyx*, or the silk-worm.

The ancients were but little acquainted with the use and manufacture of silk; they took it out of the entrails, and wound it with its feet about the little branches of trees. This insect they called *ser*, from *Seres*, a people in Scythia, whom we now call the Chinese, who, as they thought, bred it; whence the silk itself they called *sericum*. But this *ser* of theirs has very little affinity with our silk-worm, *bombyx*: the former living five years; but the latter dying annually, enveloped in a yellowish bag or ball, which, wound out into little threads, makes what we call silk.

It was in the isle of Cos that the art of manufacturing it was first invented; and Pamphila, daughter of Platis, is honoured as the inventress. The discovery was not long unknown

unknown to the Romans. Silk was brought them from Serica, where the worm was a native. But so far were they from profiting by the discovery, that they could not be induced to believe so fine a thread should be the work of a worm; and thereupon formed a thousand chimerical conjectures of their own.

Silk was a very scarce commodity among them for many ages: it was even sold weight for weight with gold; inasmuch that Vopiscus tells us, the emperor Aurelian, who died A.D. 275, refused the empress, his wife, a suit of silk, which she solicited of him with much earnestness, merely on account of its dearness.

Others, however, with greater probability, assert that it was known at Rome so early as the reign of Tiberius, about A.D. 17.

Galen, who lived about the year of our Lord 173, speaks of the rarity of silk, being no where but at Rome, and only among the rich.

Heliogabalus, the emperor, who died A.D. 220, is said by some to be the first person who wore a holosericum, *i. e.* a garment of all silk.

The Greeks of Alexander the Great's army are said to have been the first who brought wrought silk from Persia into Greece, about 323 years before Christ; but the manufacture of it was confined to Berytus and Tyre, in Phœnicia, whence it was dispersed over the West.

At length, two monks, coming from the Indies to Constantinople, in 555, under the encouragement of the emperor Justinian, brought with them great quantities of silk-worms, with instructions for the hatching of their eggs, rearing and feeding the worms, and drawing out the silk, and spinning and working it. Upon this, manufactures were set up at Athens, Thebes, and Corinth. The Venetians, soon after this time, commencing a commerce with the Greek empire, supplied all the western parts of Europe with silks for many centuries; though sundry kinds of modern silk manufactures were unknown in those times, such as damasks, velvets, fattins, &c.

About the year 1130, Roger II. king of Sicily, established a silk manufactory at Palermo, and another in Calabria; managed by workmen, who were a part of the plunder brought from Athens, Corinth, &c. of which that prince made a conquest in his expedition to the Holy Land. By degrees, Mezeray adds, the rest of Italy and Spain learned, from the Sicilians and Calabrians, the management of the silk-worms, and the working of silk; and at length the French got it by right of neighbourhood, a little before the reign of Francis I., and began to imitate them. Thuanus, indeed, in contradiction to most other writers, makes this manufacture of silk to be introduced into Sicily two hundred years later, by Robert the Wise, king of Sicily, and count of Provence.

It appears by 33 Hen. VI. cap. 5. that there was a company of silk-women in England so early as the year 1455; but these were probably employed in needle-works of silk and thread: and we find that various sorts of small haberdashery of silk were manufactured here in 1482; but Italy supplied England, and all other parts, with the broad manufacture, till the year 1489. In Spain, indeed, the culture and manufacture of silk seem to have been introduced in an early period by the Moors, particularly in Murcia, Cordova, and Granada. The silk manufactures of this last town were very flourishing, when it was taken by Ferdinand, &c. at the close of the fifteenth century.

In 1521, the French, being supplied with workmen from Milan, commenced a silk manufacture; but it was long after this time before they could obtain raw silk from the

worms; and even in the year 1547, silk was scarce and dear in France; and Henry II. is said to have been the first who wore a pair of silk knit stockings; though the first invention originally came from Spain, whence silk stockings were brought over to Henry VIII. and Edward VI. After the civil wars in France, the plantations of mulberry-trees were greatly encouraged by Henry IV. and his successors; and the produce of silk is at this day very considerable.

The great advantage which the new manufacture afforded, made our king James I. very earnest for its being introduced into England: accordingly it was recommended several times from the throne, and in the most earnest terms, particularly in the year 1608, to plant mulberry-trees, &c. for the propagation of silk-worms; but unhappily without effect; though from the various experiments we meet with in the Philosophical Transactions, and other places, it appears that the silk-worm thrives and works as well, in all respects, in England, as in any other part of Europe.

However, towards the latter end of this king's reign, *i. e.* about the year 1620, the broad silk manufacture was introduced into this country, and prosecuted with great vigour and advantage. In 1629, the silk manufacture was become so considerable in London, that the silk-throwsters of the city, and parts adjacent, were incorporated under the name of master, wardens, &c. of the silk-throwsters; and in 1661, this company of silk-throwsters employed above forty thousand persons. The revocation of the edict of Nantes, in 1685, contributed in a great degree to promote the silk manufacture in this kingdom; as did also the invention of the silk throwing machine at Derby, in 1719; for an account of which, see *SILK, Manufacture of.*

So high in reputation was the English silk manufacture, that even in Italy, as Keyser (*Travels*, vol. i. p. 289.) informs us, in 1730, the English silks bore a higher price than the Italian.

The silk-worm is an insect not more remarkable for the precious matter it furnishes for divers stuffs, than for the many forms it assumes, before and after its being enveloped in the rich cocoon or ball which it weaves for itself. From a small egg, about the size of a pin's head, which is its first state, it becomes a pretty big worm, or caterpillar, of a whitish colour, inclining to yellow. In this state it feeds on mulberry-leaves, till, being come to maturity, it winds itself up in a silken bag, or case, about the size and shape of a pigeon's egg; and becomes metamorphosed into an aurelia: in this state it remains without any signs of life, or motion; till at length it awakes to become a butterfly, after making itself a passage out of its silken sepulchre; and, at last, dying indeed, it prepares itself, by an egg which it casts, for a new life; which the warmth of the summer weather assists it in resumming.

As soon as the silk-worm, or caterpillar, is arrived at the size and strength necessary for beginning his cocoon, he makes his web; for it is thus they call that slight tissue, which is the beginning and ground of this admirable work. This is his first day's employment. On the second, he forms his pelliculus, or ball, and covers himself almost over with silk. The third day, he is quite hid; and the following days he employs himself in thickening and strengthening his ball; always working from one single end, which he never breaks by his own fault; and which is so fine, and so long, that those who have examined it attentively, think they speak within compass, when they affirm that each ball contains silk enough to reach the length of six English miles.

In ten days' time, the ball is in its perfection; and it is now to be taken down from the branches of the mulberry-trees, where the worms have hung it. But this business requires

requires a great deal of attention; for there are some worms more lazy than others; and it is very dangerous waiting till they make themselves a passage, which usually happens about the fifteenth day.

The first, finest, and strongest balls are kept for the breed; the rest are carefully wound. If there be no more than can be well wound at once, they lay them for some time in an oven, moderately hot, or else expose them, for several days successively, to the greatest heats of the sun, in order to kill the insect; which, without this precaution, would not fail to open itself a way to go and use those new wings abroad, which it has acquired within. Ordinarily, they only wind the more perfect balls. Those that are double, or too weak, or too coarse, are laid aside; not as altogether useless, but that, being improper for winding, they are referred to be drawn out into skeins. The balls are of different colours; the most common are yellow, orange-colour, isabella, or flesh-colour. There are some also of a sea-green, others of a sulphur-colour, and others white; but there is no necessity for separating the colours and shades, to wind them apart, as all these colours are to be lost in the future scouring and preparing of the silk.

*SILK, Manufacture of.* In England, where silk is not produced in any quantities to be employed by the manufacturer, he must commence his operations upon the raw silk, with no other preparation than that of being wound off into skeins or hanks from the balls, or cocoons, which the silk-worms form.

In this state the silk is imported from those countries where it is produced, as Italy, Flanders, Spain, Portugal, Turkey, the East Indies, and China. A thread of this raw silk, drawn from the skein, is found to be composed of an assemblage of several of the fine fibres or threads produced by the worms; the fibres being united together by a natural gum, which is in the silk, and which is soluble in the hot water in which the cocoons are immersed when the silk is wound off.

To prepare this raw silk for use, it is wound from the skeins upon bobbins; the compound thread is then twisted, to unite the constituent fibres more firmly than they can be by the gum alone; and afterwards, being wound again upon fresh bobbins, two or three threads are twisted together to produce a stronger thread, fit for the weaver, who warps and finally weaves the silk into various articles of ornaments or utility, by processes very similar to the weaving of cotton or linen, but more delicately conducted.

In the countries where the silk is produced, the manufacture may be more properly said to commence with the operation of winding or reeling off the threads into skeins from the cocoons, or balls, in which the worms envelope themselves. These balls become an article of trade, as soon as the insect within them is killed by exposing them to heat, either of the sun, or in an oven, or by the steam of boiling water; and, in general, the breeders of silk-worms sell them, in this state, to persons who make a business of the operation of winding. In Piedmont, where capital silk is produced, it is conducted, as follows, by the aid of the silk reel represented in *Plate Silk Manufacture, fig. 1.*

The balls are thrown into hot water, contained in a copper basin or boiler, A, which is about eighteen inches in length and six deep, set in brick-work, so as to admit a small charcoal fire beneath it; or if a fire of wood is intended to be made, the fire-place must have a small flue or chimney of iron plate to carry off the smoke. At the side of the boiler is placed the reel, which is very simple. BB marks the wood-framing which sustains its parts: these are, the reel D,

upon which the silk is wound; the layer *a*, which directs the thread upon it; and the wheel-work *b c*, which gives motion to the layer. The reel, D, is nothing more than a wooden spindle, turned by a handle at the end; and within the frame, at each end, it has four arms mortised into it, to support the four battens or rails on which the silk is wound. The rails are parallel to the axis, and at such a distance, that they will form a proper-sized skein by the winding of the silk upon them, (it is usually a yard for each revolution.) One of each of the four arms is made to fold in the middle of its length with hinges, so as to cause the rail, which these two arms support, to fall in or approach the centre, and thus diminish the size of the reel, and admit the skeins of silk to be taken off at the end of the reel when the winding is finished.

Upon the end of the wooden spindle of the reel, and within the frame B, is a wheel of twenty-two teeth, to give motion to another wheel, *c*, which has about twice the number of teeth, and is fixed upon the end of an inclined axis, *c b*; this, at the opposite end, carries a wheel, *b*, of twenty-two teeth, which gives motion to an horizontal cog-wheel of thirty-five teeth. This wheel turns upon a pivot fixed in the frame, and has a pin fixed in it, at a distance from the centre, to form an eccentric pin or crank, and give a backward and forward motion to the slight wooden rail or layer *a*, which guides the threads upon the reel: for this purpose, the threads are passed through wire-loops or eyes, *a*, fixed into the layer, and the end thereof opposite the wheel and crank, *b*, is supported in a mortise or opening made in the frame, B, so that the revolution of the crank will cause the layer to move, and carry the threads alternately towards the right or left. There is likewise an iron bar, *e*, fixed over the centre of the boiler at *e*, and pierced with two holes, through which the threads pass to guide them.

To describe the operation of reeling, it should be understood, that if the thread of each ball or cocoon was reeled separately, it would be totally unfit for the purposes of the manufacturer; in the reeling, therefore, the ends or threads of several cocoons are joined, and reeled together out of warm water, which softens their natural gum, and makes the fibres stick together, so as to form one strong smooth thread; and as often as the thread of any single cocoon breaks or comes to an end, its place is supplied by a new one, so that by continually keeping up the same number, the united thread may be wound to any length. The single threads of the newly added cocoons are not joined by any tie, but simply laid on the compound thread, to which they will adhere by their gum; and their ends are so fine, as not to occasion the least perceptible unevenness in the place on which they are laid.

The woman who conducts the reeling is seated before the basin A, and employs a boy or girl to turn the handle of the reel: a fire is lighted beneath the basin A; and when the water becomes nearly boiling hot, she throws into the basin two or three handfuls of cocoons, and leaves them some minutes, to soften that natural gum with which the silk is impregnated; then she stirs up or brushes the cocoons with a wisk of birch or of rice-straw, about six inches long, cut stumpy, like a worn-out broom; the loose threads of the cocoons stick to the wisk, and are drawn out: she then disengages these threads from the wisk, and by drawing the ends through her fingers, cleans them from that loose silk which always surrounds the cocoon, till they come off entirely clean: this operation is called *la battue*: and when the threads are quite clean, she passes four or more of them, if she intends to wind fine silk, through each of the holes in the thin iron

iron bar *c*, which is placed horizontally over the centre of the basin A; afterwards she twists the two compound threads (which consist of four cocoons each) twenty or twenty-five times round each other, that the four ends in each thread may the better join together by crossing each other, and that the thread of the silk may be round, which otherwise would be flat.

The threads, after passing through the holes in the iron bar *c*, and being twisted together, are passed through the eyes of the loops, *a*, of the layer, and thence being conducted to the reel, are made fast to one of its rails. The child who turns the reel, gives it the most rapid movement possible, and thus draws off the threads from the cocoons in the basin A. The slow traversing motion of the layer prevents the threads lying over each other upon the reel, until it has made so many revolutions in the air as to dry the gum of the silk so far, that the threads will not adhere together. After the reel is covered for about the breadth of three inches, by the gradual progression of the layer, it returns and directs a second course of threads over the first laid, and so on until the required length for the skeins is obtained. The machine winds two skeins at one time. As it is essential to the production of good silk, that the thread should have lost part of its heat and gummyness before it touches the bars of the reel, the Piedmontese are by law obliged to have a distance of thirty-eight French inches between the guides, *a*, and the centre of the reel; and the layer must also, under a penalty, be moved by cog-wheels instead of an endless cord, which is sometimes used in Italy, and which, if suffered to grow slack, will cause the layer to stop and not lay the threads distinctly, and that part of the skein will be glued together, whereas the cog-wheels cannot fail.

When the skeins are quite dry the reel is removed from the frame, and by the folding of two of its arms the skeins are taken off. A tie is made with some of the refuse silk on that part of each skein where it bore upon the bars of the reel, and another tie on the opposite part of the skein; after which it is doubled into a hank, and usually tied round near each extremity, when it is laid by for use or sale.

This operation appears very simple, but to produce a good thread requires much attention. The reeler must not wait until the thread of a cocoon is entirely exhausted before she joins on another, because the threads near the end have not above a quarter of their full thickness. The cocoons produce a very unequal length; some may be met with which yield 1200 ells, whilst others will scarcely afford 200 ells. In general, the production of a cocoon may be estimated from 500 to 600 ells in length. As often as the cocoons she winds are exhausted, or break, or only diminish, she joins fresh ones to keep up the requisite number, or the proportion; because, as the cocoons wind off, and the thread becomes finer, she must join two cocoons half wound to replace a new one. Thus she can wind three new ones and two half wound, and the silk will be equal to that produced from four to five cocoons. When she would join a fresh thread she must lay one end on her finger, throw it lightly on the other threads which are winding, and the gum will join it immediately, and it will continue to go up with the rest. She must not wind off her cocoons to the last, because when they are near at an end the husk of the worm joins in with the other threads, and makes the silk foul and gouty. The silk may be wound of any size from one cocoon to 100, but it is difficult to wind more than thirty in a thread.

The nicety of the operation, and that part in which lies the greatest difficulty, is to wind an even thread, because as the cocoon winds off the end is finer, and other cocoons must be joined on to keep up the same size. This difficulty

of keeping the silk always even is so great, that (excepting a thread of two cocoons, which is called *luch*) they do not say a silk of three, four, or six cocoons; but a silk of three to four, four to five, or six to seven cocoons. In a coarser silk it cannot be calculated even so nearly as to four cocoons more or less; they say, for example, from 12 to 15, from 15 to 20, and so on.

During the operation of winding, the woman must always have a bowl of cold water by her, to dip her fingers in, and to sprinkle frequently upon the iron bar *c*, that the heat of the basin may not burn the threads, also to cool her fingers every time she dips them in the hot water, and to pour into the basin when necessary, that is, when the water begins to boil. The water must be just in a proper degree of heat; for when it is too hot, the thread is dead, and has no body; and when too cold, the ends which form the thread do not join well, and form a harsh silk. The heat of the water from which the cocoons are wound, causes that adhesion of the fibres which compose the silk: a thread can with difficulty be wound off when cold water is employed; but in this manner the adhesion is very slight, and the thread breaks with a slight force, or the least moisture will separate the fibres; but the silk wound from hot water cannot be separated except by hot water.

The old cocoons require the water to be very hot: if the threads break very frequently, it may be concluded that the water is too cold; or, on the other hand, if the silk comes off entangled, and in the state of wool, the water is too hot. When the first parcel of cocoons is finished, the basin, A, is cleaned, taking out all the striped worms, as well as the cocoons, on which there remains a little silk: these are thrown into a basket, into which the loose silk that comes off in making the battue is likewise put as waste silk, to be carded and spun into threads. The water in the basin must be changed four times a day for coarse silk, and twice only for good cocoons of fine silk: if the water is not changed, the silk will not be so bright and glossy, because the worms contained in the cocoons foul it very considerably. The reeler must endeavour to wind as much as possible with clear water, for if there are too many worms in it, the silk will be covered with a kind of dust, which afterwards attracts moths, which destroys the silk.

From the gummy or viscid material which silk gives out to water when the cocoons are infused in it, Chappe found that he was able to blow up the water into bubbles, or small balloons, far more permanent than those of soap and water, and offering all the colours of the rainbow. So close, indeed, is the texture of these silky bladders, that even the most subtil gas does not penetrate them. Chappe filled many of them, the diameter of each not exceeding three inches, with hydrogen gas, and found several of them continued in a state of suspension, in an apartment, for considerably more than twenty-four hours. It is not all silk, however, that is sufficiently glutinous for this purpose; that which is of a very deep yellow will not answer the same purpose. This silk, from its colour, is supposed to be produced by the worm in a peculiar disease, yet this is a state by no means uncommon.

All kind of silk which is simply drawn from the cocoons by the reeling, is called raw silk, but is denominated fine or coarse according to the number of fibres of which the thread is composed. In general, the raw silk requires dyeing; to prepare for which the thread is very slightly twisted, to render it strong, and more able to bear the action of the hot liquor, without separating the fibres or turring up. Silk-yarn, which is employed by the weavers for the wool or worst of the stuffs which they fabricate, is composed of

two or more threads of the raw silk, slightly twisted in a machine; and the thread employed by the stocking weaver is of the same quality, but composed of a greater number of threads, according to the thickness desired. Organzine silk is composed of two, three, or four threads of raw silk twisted, and so combined as to obtain the greatest strength: for this purpose, each thread of raw silk is twisted separately upon itself by a mill: the twist is given in a right-handed direction, and extremely tight. By a second operation of twisting, two of these threads are combined together, the twist being given in a contrary direction, and not above half as tight: this forms a thread similar to a rope. This description of silk, used for the warp of stuffs, is of the utmost importance to the manufacturer, for none of the principal articles can be fabricated without it. The Italians, from whom we formerly imported the silk in the state of organzine, for a long time kept the art of throwing it a profound secret. It was introduced into this country by the enterprise and skill of Messrs. Thomas and John Lombe, the latter having, at the risk of his life, and with wonderful ingenuity, taken a plan of one of these complicated machines in the king of Sardinia's dominions, from which, on his return, they established a similar set of mills in the town of Derby. (See DERBY.) In consideration of the great hazard and expence attending the undertaking, a patent was granted to Sir Thomas Lombe in 1718, for securing to him the privilege of working organzine for the term of fourteen years; but the construction of buildings and engines, and the instruction of the workmen, took up so much time, that the fourteen years were nearly expired before he could derive any advantage from it; in consequence of which, he petitioned parliament, in 1731, to grant him a further term: but parliament, considering it an object of national importance, granted him the sum of 14,000*l.* on condition that he should allow a perfect model of the machinery to be taken, and deposited in the Tower of London for public inspection. Similar mills were, in course of time, erected in different parts of the country; but owing to the difficulties that were experienced in procuring raw Italian silk of the proper size for organzine (the exportation of which was prohibited by the Italians), and to the mills having subsequently found employment for other purposes, the quantities worked into organzine, for many years, bore scarcely any proportion to the imports from Italy; it has however been since revived and improved, in consequence of which it is now carried on to a very considerable extent, as well in other parts of England as at Derby.

The process which the silk undergoes to bring it into this state, consists of six different operations. 1. The silk is wound from the skein upon bobbins in the winding machines. 2. It is then sorted into different qualities. 3. It is spun or twisted on a mill in the single thread, the twist being in the direction of from right to left, and very tight. 4. Two or more threads thus spun are doubled or drawn together through the fingers of a woman, who at the same time cleans them, by taking out the slubs which may have been left in the silk by the negligence of the foreign reeler. 5. It is then thrown by a mill, that is, the two threads are twisted together, either slack or hard, as the manufacture may require; but the twist is in an opposite direction to the first twist, and it is wound at the same time in skeins upon a reel. 6. The skeins are sorted according to their different degrees of fineness, and then the process is complete.

The first operation which the raw silk undergoes is winding, that is, drawing it off from the skeins in which it is imported, and winding it upon wooden bobbins, in which

state it can go to the other machines. The winding-frame is shewn at *fig. 2.* of the plate, or rather a part of it, which will wind six threads at once, and by increasing the length it may be made to receive any number. Each of the skeins is extended upon a slight reel *AA*, called a swift; it is composed of four small rods, fixed into an axis, and small bands of string are stretched between the arms to receive the skein, but at the same time the bands admit of sliding to a greater or less distance from the centre, so as to increase the effective diameter of the reel, according to the size of the skein, because the skeins, which come from different countries, vary in size, being generally an exact yard, or other similar measure, of the country where the silks are produced. The swifts are supported upon wire pivots, upon which they turn freely when the silk is drawn off from them; but in order to cause the thread to draw with a gentle force, a looped piece of string, or wire, is hung upon the axis within the reel, and a small leaden weight, *c*, being attached to it, will cause a sufficient friction. *B, B,* are the bobbins which draw off the threads; they are received in the frame, and are turned by means of a wheel beneath each, the bobbin having a small roller upon the end of it, which bears by its weight upon the circumference of the wheel, and the bobbin is thereby put in motion to draw off the silk from the swift. *D* is the layer, a small light rod of wood, which has a wire-eye fixed into it, opposite to each bobbin, so as to conduct the thread thereupon; and as the layer moves constantly backwards and forwards, the thread is regularly spread upon the length of the bobbin. The motion of the layer is produced by a crank fixed upon the end of a cross-spindle, *E*, which is turned by means of a pair of bevelled wheels from the end of the horizontal axle, upon which the wheels for turning all the bobbins are fixed.

These winding-machines are usually situated in the top building of the mill, the frames being made of great length, and also double, to contain a row of bobbins and swifts at the back as well as in front. Two of these double frames are put in motion by cog-wheels from the vertical shaft, *F*, which ascends from the lower apartments of the mill, where the twisting-machines are placed. The winding-machines require a constant attendance of children to mend the ends or threads which are broken; or when they are exhausted, they replace them by putting new skeins upon the swifts. When the bobbins are filled they are taken away, by only lifting them up out of their frame, and fresh ones are put in their places.

A patent has been lately taken out by Messrs. Gent and Clarke, for a new construction of the swifts for winding-machines: they are made with six single arms instead of four double ones; and the arms are small flat tubes, made to contain the stems of wire forks, which receive the skein instead of the bands of string in the common swifts. These forks admit of drawing out from the tubes until the swift is sufficiently enlarged to extend it; but as they extend the skein at six points instead of four, as in the common one, the motion is more regular. Instead of the weight which causes the friction, a spring is used to press upon the end pivot of the axis, and make the requisite resistance.

The twisting of the silk is always performed by a spindle and bobbin, with a flyer, but the construction of the machine which puts the spindle in motion is frequently varied. The limits of our plate do not admit a representation of the great machines, or throwing-mills, such as are used at Derby, and at almost all the other great silk-mills in England. In *fig. 3.* we have given a drawing of a small machine, which is similar in the parts which act upon the silk; and indeed many mills employ such machines constructed on a large scale.

The one in our plate contains only thirteen spindles, and is intended to be turned by hand, a method which is too expensive for this country, but is common in the south of France, where many artificers purchase their silk in the raw state, and employ their wives or children to prepare it by these machines, which they call ovals, because the spindles *b, b*, are arranged in an oval frame, G H. B is the handle by which the motion is given; it is fixed on the end of a spindle, R, which carries a wheel, D, to give motion to a pinion upon the upper end of a vertical axle, E: this, at the lower end, has a drum or wheel F, to receive an endless strap or band, *a a*, which encompasses the oval frame G, and gives motion to all the spindles at once. The spindles *b, b*, are placed perpendicularly in the frame G H, their points resting in small holes in pieces of glass, which are let into the oval plank G; and the spindles are also received in collars affixed to an oval frame H, which is supported from the plank, G, by blocks of wood; *d* and *a* are small rollers, supported in the frame G H, in a similar manner to the spindles: their use is to confine the strap, *a*, to press against the rollers of the spindles with sufficient force to keep them all in motion.

The thread is taken up as fast as it is twilled by a reel, K, which is turned by a wheel, *b*, and a pinion, *i*, upon the end of the principal spindle, R. The threads are guided by passing through wire-eyes, fixed in an oval frame, L, which is supported in the frame of the machine by a single bar or rail, *ll*, and this has a regular traversing motion backwards and forwards, by means of a crank, or excentric pin, *k*, fixed in a small cog-wheel, which is turned by a pinion upon the vertical axis E; the opposite end of the rail, *l*, is supported upon a roller, to make it move easily. By this means the guides are in constant motion, and lay the threads regularly upon the reel K, when it turns round, and gathers up the silk upon it, as shewn in the figure.

One of the spindles is shewn at *r* without a bobbin, but all the others are represented as being mounted and in action. A bobbin, *e*, is fitted upon each spindle, by the hole through it being adapted to the conical form of the spindle, but in such manner, that the bobbin is at liberty to turn freely round upon the spindle: a piece of hard wood is stuck fast upon each spindle, just above the bobbin, and has a small pin entering into a hole in the top of the spindle, so as to oblige it to revolve with the spindle; this piece of wood has the wire-flyer, *b*, fixed to it: the flyer is formed into eyes at the two extremities; one is turned down, so as to stand opposite the middle of the bobbin *e*; and the other arm, *b*, is bent upwards, so that the eye is exactly over the centre of the spindle, and at a height of some inches above the top of the spindle. The thread from the bobbin, *e*, is passed through both the eyes of this wire, and must evidently receive a twist when the spindle is turned; and at the same time, by drawing up the thread through the upper eye, *b*, of the flyer, it will turn the bobbin round and unwind therefrom. The rate at which the thread is drawn off from the bobbin, compared with the number of revolutions which the flyers make in the same time, determines the twist to be hard or soft; and this circumstance is regulated by the proportion of the wheel, *b*, to the pinion *i*, from which it receives motion; and these can be changed when it is required to spin different kinds of silk. The operation of the machine is very simple; the bobbins filled with silk in the winding-machine, *fig. 1*, are put loose upon the spindles at *e*, and the flyers are stuck fast upon the top of the spindles: the threads are conducted through the eyes of the flyers *b*, and of the layers L, and are then made fast to the reel K, upon which it will be seen that there are double the number of skeins to that of the spindles represented, because

one half of the number of the spindles is on the opposite side of the oval frame, so that they are hidden. With this preparation the machine is put in motion, and continues to spin the threads by the motion of the flyers, and to draw them off gradually from the bobbins, until the skeins upon the reel are made up to the requisite lengths. This is known by a train of wheel-work at *n o p*, consisting of a pinion, *n*, fixed upon the principal spindle R, turning a wheel *o*, which has a pinion fixed to it, and turning a larger wheel *p*; this has another wheel upon its spindle, with a pin fixed in it, which at every revolution raises a hammer, and strikes upon a bell, *s*, to inform the attendant that the skeins are made up to a proper length. When this machine is employed for the first operation of twilling the orgauzine, the wheel, *b*, must be larger, and the pinion, *i*, smaller than represented, in order that the reel, K, may be turned slowly, and the threads will therefore receive a stronger and closer twist. Also, the handle B is turned in an opposite direction to that in which it must move for the final throwing off the two or three twilled threads together; and as it must also move for twilling the raw threads together for the warp of silk-stuffs, and for weaving stockings, this reverse movement makes no alteration in the machine, except that it will give twist in a contrary direction; for it is always necessary, when two or more twilled threads are combined by twilling, that the twill of the original threads shall be in the opposite direction to that twist which unites them into one thread, in the same manner as for making ropes, orgauzine silk being in fact small rope, and stocking-silk or warp being only yarn. The silk which is intended to be dyed, is previously twisted very slightly in this machine, and of course in that direction which will suit the purpose for which it is ultimately intended; *viz.* whether for yarn or orgauzine.

The great mills for twilling silk, originally introduced by Messrs. Lombe, though very complicated, are simple in their operation, because the complexity arises from the great number of spindles which are actuated by the same movement, every one of which produces its effect independent of the others, and in the same manner as the oval which we have described. A machine is contained in a circular frame, of which the diameter varies from 11 to 13, 15, and even 17 feet; but 15 feet is the general size of the original Piedmontese machines. In the centre of the frame is a perpendicular axis or spindle, coming up through the floor of the chamber, and rising to the ceiling; it is put in motion by a communication of wheel-work from a water-wheel, or otherwise from a horse-wheel. The axis has upon it two, three, or four horizontal wheels, according to the height of the machine, which revolve with it, and are of a sufficient size to fill nearly all the interior of the circular frame, and act upon the pulleys or rollers of the spindles, which are supported vertically in the frame, and arranged round the machine, at equal distances, in a circle, the number being proportioned to the dimensions of the machine. The spindles are also arranged in as many different stages of height as there are wheels upon the vertical spindle; for the circumference of each wheel presses against the rollers of the spindles which are arranged round it; and thus, when the wheel revolves, it gives a very rapid motion to all the spindles at once, by the contact of the edge of the wheel, but without any strap, as in the oval. Each spindle has a bobbin, filled with silk, fitted upon the top of it, and from this the silk is carried up to a horizontal reel, which is turned round slowly by the machine, and draws off the thread gradually from the bobbin: the flyer, being all the while in rapid motion, twists the thread upon itself, or, if two or three threads are previously wound together upon the bobbin, they will be twisted

twisted round each other. Each reel serves to take up the thread from several spindles which are situated beneath it: thus, in a mill of fifteen feet diameter, there will be six spindles beneath each reel.

To explain this machine more clearly, we will give a description of one of thirteen feet diameter, which has four large wheels and stages of spindles, two of which are for giving the first preparation to the organzine: the spindles revolve in a direction from right to left. The spindles of the other two stages are for the finishing the twist, and also for twisting the single threads which are to be used for warp or for flocking-weaving: they revolve in a contrary direction to the former. The frame of the machine consists of two wooden circles of thirteen feet diameter, one placed upon the floor of the mill, and the other at a height of fifteen feet above, the two being united by fourteen upright pillars of wood, which altogether compose a large cylindrical frame or lantern. Each stage contains eighty-four iron spindles, placed vertically, and supported in the stage, which is formed of two wooden circles, extended round between the fourteen uprights of the lantern, and fixed one above the other, at about a distance of four inches asunder, so as to support the spindles between them, in the same manner as the pieces, G, H, of the oval last described.

The circles of the stage are of a rather less diameter than the two circles which compose the top and bottom of the lantern; so that the spindles will be rather within the circle of the frame of the lantern, and admit the wheels of the central axis to act upon them. For this purpose, each of the circles of the stage is made up by fourteen segments fixed between the uprights, and each segment supports six spindles, making up the number of eighty-four in the whole circle. The spindles, like those of the oval, are sharp-pointed at the lower end, and the points rest in small holes made in pieces of glass, which are let into the lower circle of the stage, whilst the upper circle sustains the spindle at a height of four or five inches above the point, leaving full one-third of the length of the spindle projecting above, for the purpose of fitting the bobbin upon it. The upper circle of the stage is rather smaller than the lower, because the spindles do not pass through it, but through holes in small pieces of hard wood, which project from it, so as to be exactly above the pieces of glass which sustain the points of the spindles. Each spindle has a small roller fixed upon it in the space between the two circles of the stage, and it is the contact of the rim of the great wheel upon these that causes the revolution of the spindles when the wheel revolves. In order to make the contact certain, the exterior rim of the great central wheel is made in several segments, and each segment has a constant tendency to recede from the central axis by the action of a weight, and thus presses against the rollers of the spindles. In order to give the reverse movement of the spindles, which we have before spoken of in the description of the oval, the great wheels for two of the stages are made differently from those which we have just described, so that the segments of the rim will act upon the outsides of the rollers of the spindles, instead of the insides: for this purpose the wheels are made larger than the stages in which the spindles are placed, and from the rim of the wheel small pillars rise up to support the segments, which act upon the rollers of the spindles in front or withoutside of the circles, instead of the inside, as is the case with the other stages, in consequence of which the spindles of these stages turn in opposite directions. The reels are placed over the bobbins, to take up the threads when twisted; and the rollers of the different spindles are made smaller or larger, as is required, to give more or less twist to the silk

operated upon by them; for the velocity with which the spindles revolve, compared with the rate at which the reels take up the thread, determines the degree of twist which the thread will have; and to render this equable, the reels which draw off the silk from the bobbins of the spindles are turned regularly with the motion of the machine by means of wheel-work, which is more easily conceived than described: it is sufficient to state that it receives its motion from the central vertical axis. There is also a layer adapted to each reel, with a wire-eye to receive each thread; and the layers having a slowly reciprocating motion, distribute the threads regularly upon the reels, in a similar manner to that first described for the oval. One of these reels is placed between each of the uprights of the machine, so as to make fourteen reels in the whole circle of each stage, and every reel serves to take the silk from the bobbins of six spindles. The whole machine in the four stages contains 336 spindles.

A machine of four stages is so high, as to reach through two floors of the mill, and for this purpose the upper floor is made with a large round opening, to admit the machine: this floor serves the people who attend the machine, and change the bobbins when exhausted, and also remove the finished silk from the reels.

The spindles in the upper stages are usually devoted to the first twisting of the single threads for the organzine, and therefore turn the reverse way, as before mentioned; and as the silk is afterwards to be thrown, or re-twisted, they are drawn off from the bobbins by large bobbins of three inches diameter, and four inches long, instead of the reels. These bobbins are stuck six together upon a long spindle, situated horizontally, and turned by similar wheel-work to that which actuated the reels; they have similar layers to conduct the silk regularly upon the bobbins from one end to the other, so that the operation is not at all different.

In many of the best silk-mills, they have abandoned the original method of turning the spindles, for the preparation of organzine, the reverse way, by making the action of the wheels upon the outside, instead of the inside, of the circle of spindles. Instead of them they employ two different machines, one for the first operation on organzine, and the other for the second operation, both of them constructed with the wheels withinside: but the motion of the two machines is reversed to each other.

Fig. 5. represents a single spindle of a throwing machine, which, though the same in its action as the great mill, is different in its construction. G and H represent portions of the rails or circles of the stage which support the spindle, and *aa* is a part of the rim of the great wheel of the central axle. This wheel is not made in segments, as before described, but is made very truly circular, and covered with leather on the edge, that it may act with more force to turn the roller, *t*, of the spindle. The point of the spindle rests in a glass cap, supported by the rail G, and the roller, *t*, is always made to press against the rim of the great wheel, *aa*, by a small lever, *d*, and a string, which, after turning over a pulley, has the weight, *e*, made fast to it, to press the spindle always towards the wheel. In this machine, instead of the reel, the thread is taken up by a bobbin, K, is put into a frame, *m*, which moves on pivots, and by a weight, *n*, is pressed down so as to make the bobbin bear upon the edge of a wheel, *b*, which is kept in constant and regular motion, by the same kind of movement which turns the reels of the great machine. The intention of this is, that the action of the wheel, *b*, to turn the bobbin, being communicated by pressure against the part upon which the silk is to wind, will be constant,

slant, and will not draw more when the bobbin is large and full, or less when it is empty, as must be the case when the motion is given to the axis of the bobbin.

After the silk is twitted in a right-hand direction, if it is intended for yarn, or for dyeing; or in a left-hand direction, if it is prepared for organzine; it must be wound on fresh bobbins, with two or three threads together, preparatory to twitting them into one thread. In the original machines at Derby this was done by women, who, with hand-wheels, wound the threads from two or three of the large bobbins, upon which the silk is gathered instead of the reels, and assembled them two or three together upon another bobbin, of a proper size to be returned to the twitting mill. We have seen an attempt for a machine to perform the doubling, which is slightly represented in *fig. 4*. The whole machine itself is very similar to the winding-machine, *fig. 2*, but instead of the swift, the bobbins from the throwing-mill are placed in front at *A*, *fig. 4*, two or three in a row. The threads from these are pulled over the rail *m*, and beneath a piece of wood, *n*, both which, being covered with cloth, have the same effect to clean the silk by drawing through them, as the fingers of the winder. *B* is the bobbin upon which the two or three threads are to be wound together; it is turned by a wheel, *F*, upon which it rests, the same as the bobbins of the winding-machine; and *D* is the layer, which, for convenience, is in this case placed behind the bobbin, *B*; and the wire-eye, *d*, which receives the three threads, is made to reach over to the front. The additional apparatus consists of a small piece of wood, *e*, which slides freely up and down, in a hole, through a fixed board, *f*. On the top of the slider, *e*, is an eye of wire, through which one of the single threads of silk passes in its passage from between the pieces *m, n*, to the bobbin *B*: there is one of these sliders, *e*, to each of the three threads; *tv* is a lever moving on the centre *w*; the end *t* is immediately beneath the small sliders *e*, and the end *v* is formed to a hook, to catch into the notches which are made in the end of the bobbin *B*. A small counter weight, *x*, always causes the hook, *v*, of this lever to recede from the bobbin; but if any one of the three threads break, it fulsters the slider *e*, which belongs to it, to descend upon the end, *t*, of the lever, and depresses the end of the lever, so as to bring the hook, *v*, in a situation to catch a tooth of the bobbin *B*, and stop its motion. By this means the winding of three threads together is rendered equally certain with the winding of one; for when any one breaks, the operation of winding on that bobbin stops, until the attendant repairs the broken thread, and puts the machine again in motion. We have lately been informed, that a machine for winding two and three threads together is becoming common in the silk-mills, but we do not know if it is the same with this one, which however is not evidently impracticable.

The bobbins, being thus filled with double or triple threads, are carried back to the throwing machine, and are there spun or twitted together, the manner of doing which does not differ from the operation which we have before described. In this second operation the silk is taken up by reels instead of bobbins, and is thus made up into skeins. The degree of twill varies with the purpose for which the silk is intended; and the wheels which give motion to the reels are for this purpose adapted to the degree of twill which the silk is desired to have. The silk, being now spun, requires only the preparation of boiling to discharge the gum, and render the silk fit to receive the dye, and also to render it soft and glossy. The silk is boiled for about four hours, in a boiler filled with water, into which a small quantity of soap is put; this opera-

tion dissolves the gum, which before could be felt upon the silk, and rendered it harsh. After the boiling, it is well washed in a current of clear water, and when dried, will be found to have lost about one-fourth of its weight: at the same time the volume of the silk is sensibly increased, and it has acquired that soft texture and glossiness, which are the principal beauties of silk. This change is produced by the dissolution of the gum, which, in the first instance, was the only adherence of the fibre to form a thread, but by the operation of the twitting the fibres are firmly united, and no longer require the gum. It is also necessary, in order to give a fine dye to the silk, that the gum should be removed, because it would prevent the entrance of the dyeing matter to the centre of the thread, and thus impair the beauty of the colour. If the silk was thus boiled before the twitting, nothing but a fine entangled down or wool would be obtained, and it would require spinning, by a similar process to that of cotton, before a thread could be obtained. This, indeed, is necessary for that portion of waste silk which is drawn from the cocoons in the first operation of reeling; also for those cocoons which are reserved for breeding, and from which the moths eat their way out by holes, which render it impracticable to wind off the silk. This waste silk, when carefully spun by a spinning-wheel, is called spun silk, and the thread is not inferior to the regular silk which is wound off: indeed, the winding off the silk into a thread united by its gum, is of no advantage farther than as a preparation for spinning, from which process the thread obtains its strength.

The silk is now in a state for use: if it is for stocking-weaving, or sewing, or if intended for weaving into stuff, it only requires warping to be put into the loom. The operation of warping is to put together all the threads which are to compose the warp of the intended piece of stuff, and lay them parallel, so that the warp, being put into the loom, will have no slack threads, nor any which are strained too tight. Formerly, this operation was performed by stretching the threads out at length in a field, or by extending them in a frame, and winding them backwards and forwards over pegs. The warping machine now universally employed is shewn in *fig. 6*, where *AA* is a tressel or stool, which supports the small bobbins *b, b*, upon which the silk is wound. The number of these is equal to the number of threads which the warp of the intended piece of stuff is to have in its breadth. The threads from all these bobbins are drawn over wires *d, d*, which are in front of the bobbins, and are then all brought together, and passed through an opening in a piece of wood *D*; this conducts the threads all together upon a large reel *E, E*, which is supported in a frame *F, F, F*, and turned round by means of a pulley at the lower end of its axle, from which an endless band is continued to a second wheel *G*, mounted on a spindle, and turned by a handle. This latter spindle is supported in a sort of stool *H*, upon which a child sits down, and at the same time turns the handle and puts the reel in motion, so as to draw the warp or assemblage of threads off from the several bobbins, and lay it upon the reel *E*. The piece of wood *D* is fitted upon one of the upright pieces, *F*, of the frame, to slide freely up and down upon it, and is suspended by a cord, which, after passing over a pulley *f*, is wrapped round the spindle of the machine at *e*: by this means, the motion of the reel, *E*, draws the cord, and raises up the piece *D*, so as to lay the warp upon the circumference of the reel, in a regular spiral, from one end to the other, and prevent the coils lapping one upon another. When the required length of warp is wound upon the reel, the ends of all the threads are cut off, tied together, and thus drawn off from the reel and rolled up into a large ball,

in which the weaver takes it, and mounts it in his loom.

For the subsequent operations of weaving we shall refer to the article WEAVING, because the weaving of silk goods is the same as for any other, except that finer and more beautiful articles are produced in this substance than in any other. Some information on the details of weaving mechanism will be found under our articles DRAUGHT of Looms, DRAW-LOOM, DIAPER, DIMITY, and DORNOCK; and though these are rather the weaving of linen and cotton than silk, the same principles apply to silk, as will be more fully explained under WEAVING; where a description of weaving ribbands and figured silks will be given.

Silk is distinguished by different names according to its different states. Thus,

**SILK, Spun**, is that taken from the ball, without fire, and spun into thread without any coction: such as is most, if not all, that is brought into England from the Levant; *i. e.* from Persia by the way of Turkey, from Bengal in India, and from China. The raw spun silk is commonly worked up into two sorts, called *organize* and *tram*: the former is made by giving a throw or twist to each thread of raw spun silk singly, and then doubling two of these twisted threads together, and twisting them smartly together; this forms the warp or length of a piece when manufactured. The tram, or shoot, which makes the breadth of the piece, is formed by twisting two or more threads of raw silk slack. The waste raw silk, or refuse in reeling, &c. is collected, carded, and spun, and called *stoss* silk; this is doubled and thrown, and often made into a cheap sort of silk-stockings, which are very strong and durable.

In the French silk-works, the greatest part of this raw silk passes for little better than a kind of fine floretta; yet, when spun, it makes a bright thread, and serves for the manufacture of stuffs of moderate value and lustre. But the spun silks of the Levant, whence most of our's come, are exceedingly fine and beautiful. The difference arises hence, that in France, the best balls are reeled off in boiling water, and only the refuse made into spun silk; whereas, in the Levant, there is no such thing as reeling or winding on the fire, but the silks are all sent in bales, or packs, as they are drawn from off the balls; so that they are only distinguished by their quality of fine, middling, and coarse.

**SILK, Boiled**, is that which has been boiled in water, to facilitate the spinning and winding. This is the finest of all the sorts of silk manufactured in France, and is seldom used but in the richest stuffs; as velvets, taffeties, damasks, brocades, &c.

There is also another kind of boiled silk, which is prepared by boiling, to be milled; and which cannot receive that preparation, without being first passed through hot water. By the laws of France, it has been prohibited to mix raw with boiled silk; both as such a practice spoils the dyeing, and as the raw silk corrupts and cuts the boiled.

**SILKS, thrown or twisted**, are such as, besides their spinning and winding, have received their milling or throwing.

This they receive in a different degree, as they are passed oftener or seldomer over the mill; properly, however, thrown silks are those in which the threads are pretty thick-thrown, and twisted several times.

The thrown silk comes to us chiefly from Leghorn, Genoa, Naples, and Messina.

**SILKS, Slack**, are such as are not twisted, but are prepared, and dyed for tapettry, and other works with the needle.

**SILK, Eastern or East Indian**. That popularly thus called is not the work of the silk-worm, but comes from a plant that produces it, in pods, much like those of the cotton-

tree. The matter this pod contains is extremely white, fine, and moderately glossy; it spins easily, and is made into a kind of silk, that enters the manufacture of several Indian and Chinese stuffs.

**SILKS, French**. It is only in the most southern provinces of France that silk is cultivated, mulberry-trees planted, and worms bred. The principal places are Languedoc, Dauphiné, Provence, Avignon, Savoy, and Lyons. This last place, indeed, furnishes very few silks of its own growth; but it is the great staple whence the merchants of Paris, and the other cities, are to fetch them. At least, they are obliged to have them pass through Lyons, if they bring them from other places, either by land or sea. There have been computed to enter Lyons, *communibus annis*, six thousand bales; the bale valued at one hundred and sixty pounds weight; of which six thousand bales, there are one thousand four hundred from the Levant, one thousand six hundred from Sicily, one thousand five hundred from Italy, three hundred from Spain, and one thousand two hundred from Languedoc, Provence, and Dauphiné.

At the time when the manufactures of Lyons were in their prosperity, there were reckoned to be eighteen thousand looms employed in the silk manufacture; but in 1698, there were not reckoned four thousand. However, this manufacture afterwards revived, and a great part of Europe has been supplied from hence with brocade and rich silks. The decay has not been less notable at Tours; they had formerly there eight hundred mills for winding and preparing the silks; eight thousand looms to weave them; and forty thousand persons employed in the preparation and manufacturing of them; but these have been reduced to seventy mills, twelve hundred looms, and about four thousand persons. The revolution has, however, made such an alteration in the manufactures and trade of France, and they are still (1816) in so unsettled a state, that no correct estimate of them can be obtained.

**SILKS, Sicilian**. The commerce of the silks of Sicily has been very considerable; and the Florentines, Genoese, and Luccese, are the people who have chiefly availed themselves of it. Great quantities were yearly brought thence, especially from Messina; part of which they used in their own manufactures, and sold the rest to their neighbours the French, &c. with profit. The Italians had this advantage, especially the Genoese, over other people, that, having large establishments in the island, they were reputed as natives, and paid no duty for the export.

Part of the Sicilian silks is raw, the rest are spun and milled; of which last kind, those of St. Lucia and Messina are the most valued. The raw unwrought silks were always sold for ready money; the others, sometimes, in exchange for other goods. See SICILY.

**SILKS, Italian**. The silks brought from Italy are partly wrought, and partly raw and unwrought. Milan, Parma, Lucca, and Modena, furnish none but the latter kind; Genoa most of the former; Bologna affords both kinds. The finest Italian wrought silk comes from Piedmont, Novi, Bergamo, and Bologna; and is imported into England from the ports of Nice, Genoa, and Leghorn.

The silk we have from Italy is generally thrown, and serves for warp for our manufactures.

**SILKS, Spanish**, are all raw; and are spun, milled, &c. in England, according to the several works in which they are to be used.

**SILKS, Turkey**, are all raw. One advantage we have in the commerce of the Levant, in silks, wanting in those of Sicily, is, that the latter are confined to a particular season of the year; whereas the former are bought at all times.

They

They are brought from Aleppo, Tripoli, Sayda, and from the isle of Cyprus, Candia, &c. But the principal place of commerce, especially for the silks of Persia, is Smyrna. The silks are brought hither in caravans, from the month of January to September. The caravans in January are laden with the finest silks; those of February and March being indifferent ones; the rest, the coarsest. They all come from the several provinces of Persia, chiefly those of Ghilan and Shirvan, and the city of Schamachia, situate near the edge of the Caspian sea; from which three places, a Dutch author assures us, there have not come less than thirty thousand bales of silk in a year. Ghilan produces the best and greatest quantities of silk; next to this are Shirvan and Erivan, then Mazanderan, and lastly Astrabad; but the latter is much inferior, serving only for a manufacture mixed with cotton; that of Mazanderan and Astrabad is seldom or ever exported.

Ardeuil, or Ardebil, another city of Persia, not far distant from these silk countries, is the place where silks are laid up, and whence the caravans set out for Smyrna, Aleppo, Scanderoon, and Constantinople; and it is this city, with Schamachia, that have always been esteemed the centre of the silk trade; which has been several times attempted to be removed from Smyrna, and the Mediterranean, in favour of Archangel, and the White sea, by carrying them across Muscovy, by the Volga and Dwina, two rivers that traverse the principal provinces of that vast empire.

This new course of the Persian silks into Europe was first proposed by Paolo Centurio, a Genoese, to the czar Basil, under the pontificate of Leo X. The French had the same design in 1628. The duke of Holstein, in 1633, sent ambassadors to the court of Persia, purely with the same view. And in 1668, the czar Alexis Michael attempted the thing himself; but he was disappointed by the rebellion of the Cossacks, and the surprize of Astrakhan.

In 1688, the commerce of Persian silks had nearly been removed from Smyrna by an earthquake, which almost overturned the whole city; and, doubtless, the removal had been effected, but for the vigorous means used by the Turks to prevent it. Smyrna, however, still remains in her ancient possession; and the several nations of Europe continue every year to send their fleets, to fetch away the silks.

**SILKS, China, Japan, and Indian.** Several provinces of China are so fertile in mulberry-trees, and their climate is so agreeable to the nature of silk-worms, that the quantity of silks there produced is incredible; the single province of Telehiang might supply all China, and even a great part of Europe, with this commodity. The silks of this province are the most esteemed, though those of Nankin and China be excellent.

The silk-trade is the principal in China, and that which employs the most hands; but the European merchants who deal in it, especially in wrought silks, are to be careful of the spinning, &c. the waste being usually very great, as the French East India company have found to their cost.

Japan would not afford fewer silks than China; but that the Japanese, a barbarous and distrustful people, have interdicted all commerce with strangers, especially with Europeans, excepting with the Dutch; who are said to be admitted on certain impious terms, related by Tavernier, but which, we must own, we cannot credit. The Dutch have endeavoured to vindicate themselves from these by the pens of several famous writers.

Great quantities of both raw and wrought silk are furnished by other parts of Bengal, and by several provinces of

Hindoostan, which partly supply the natives, and afford a very considerable exportation to Europe. Several thousand bales of raw silk are annually imported from Bengal and China; some of which is, in this state, used for making princes' fluffs, but the greater part is prepared for the manufacturers by the silk-throwsters.

**SILK, *Larus relating to.*** The duties on silks and calicoes being under the same regulations with those on printed lincens, the law respecting them is inserted under the article **LINEN.** By the 13 & 14 Car. II. c. 15. s. 2. no person shall exercise the trade of a silk-throwster, unless he hath served seven years' apprenticeship, on pain of 40s. a month, half to the king, and half to him that shall sue in any court of record, or at the assizes, or quarter-sessions of the peace. By 9 & 10 W. c. 43. no foreign silks, called alamodes or luteiftings, shall be imported but in the port of London, on notice first given to the commissioners of the customs, and licence had from them, on pain of forfeiture, or the value; and they shall be sold, and exported again; and the offender so importing, and also the receiver and person offering to sell the same, shall forfeit 500*l.* Being marked and sealed by order of the commissioners, any person who shall counterfeit the custom-house seal, or that of the luteifring company, shall forfeit 500*l.*, and be set in the pillory for two hours. And any person who shall buy and sell, and have in his custody, any alamodes or luteiftings, sealed or marked with a counterfeit seal or mark, shall forfeit the same and 100*l.*

However, none but custom-house officers, or persons deputed by the luteifring company, and having writs of assistance under the seal of the exchequer, shall seize luteiftings or alamodes within the bills of mortality. (5 Ann. c. 20.) The penalties shall be two-thirds to the king, and one-third to him that shall seize or sue in any court of record.

By 3 Geo. III. c. 21. and 5 Geo. III. c. 48. if any person shall import any ribbands, laces, or girdles, not made in Great Britain, whether the same shall be wrought of silk alone, or mixed with other materials, the same shall be forfeited, and may be seized by any officer of the customs, in whatever importers', venders', or retailers' hands they may be found; and the importer, and every person assisting therein, and the venders and retailers in whose custody they shall be found, or who shall sell or expose the same to sale, or conceal with intent to prevent the forfeiture, shall forfeit respectively 200*l.*, with costs. Half the said penalties to be to the king, and half to the officer who shall inform and prosecute.

But if any officer of the customs shall neglect or refuse, for one month after condemnation, to prosecute to effect any person for any of the said pecuniary forfeitures, any other person may sue for and recover the same; half thereof to go to the king in like manner, and half to him who shall sue.

And when the goods seized (being out of the limits of the bills of mortality) shall not exceed the value of 20*l.*, two justices, on information before them that such goods were seized, as unduly imported, may hear and determine the same, and proceed to condemnation or discharge.

After seizure, until condemnation or discharge, the said goods shall be deposited in one of the king's warehouses, if the seizure be within the bills of mortality; elsewhere, in the hands of the chief magistrate or constable; and the same shall be free to inspection, with leave of the court, judge, or justices, before whom the prosecution shall be.

And after condemnation, the said goods shall be publicly sold by the candle for exportation; half of the produce by

such sale to be to the king, and half to the officer who shall seize and secure the same; and the same goods shall not be delivered out of the warehouse, till security shall be given for exportation, and that the same shall not be landed again in any part of his majesty's dominions.

By 5 Geo. III. c. 48, if any foreign manufactured silk-sockings, silk-mitts, or silk-gloves, shall be imported into this kingdom, or any part of the British dominions, the same shall be forfeited, and liable to be searched for and seized as other uncustomed goods; and every person who shall import the same, or be assisting therein, and the vendors and retailers in whose custody they shall be found, or who shall sell or expose the same to sale, or conceal with intent to prevent the forfeiture, shall, over and above the forfeiture of the goods, forfeit 200*l.*, with costs; half to the king, and half to the officer who shall inform and prosecute.

And when the goods seized (being out of the limits of the bills of mortality) shall not exceed the value of 20*l.*, two justices may proceed to the condemnation thereof. And the proceedings, in all other respects, shall be in like manner as in the case of ribbands and laces above mentioned.

SILK, in *Chemistry*, deserves notice on account of a peculiar salt, or crystalline substance, obtained from it by the nitric acid. In its natural state, or before it is bleached, it contains a yellow resinous matter, from which it derives its fine golden colour. When raw silk is infused in water, a portion of gummy matter is dissolved, and a light amber-coloured liquor is produced. Pure alcohol extracts a much deeper yellow colour, and makes a tincture, that loses none of its colour by long exposure to the sun, which bleaches the silk itself. Nitrous acid acts powerfully on silk, in proportion to its concentration. If two drachms of this acid are mixed with a pint of alcohol, and silk, either raw or bleached, be immersed in it, and kept in digestion, in a moderate warmth, for twenty-four hours, the silk becomes of a dull yellowish-brown, which, after rinsing and washing with soap, and drying, turns to a fine golden yellow, which is very permanent. But when concentrated nitric acid is distilled off silk, and the remaining liquor duly evaporated, much oxalic acid is obtained; and the residue, if evaporated still further, yields, together with a little remaining oxalic acid, a quantity of yellow granular crystals, very bitter, not acid, and staining the saliva and hands of a very deep yellow, not easily removed. If the liquor is previously saturated with potash, and evaporated, another yellow silky salt evaporates, which detonates on coals like common nitre, and appears to be a triple combination of the former bitter substance with nitrate of potash. The first mentioned granular crystals, examined with a magnifier, appear to be composed of truncated octohedrons.

The above curious substance was discovered by Welter, and called by him the "bitter principle." He supposes it to be generally produced by the action of nitric acid on animal matters; and it is perhaps the same substance which causes the bitterness of bile. Aikin.

The spirit of raw silk, rectified with some essential oil, is the medicine commonly known by the name of *Gutta Anglicana*, or English drops.

SILK, *Spider*. Within about a century the secret has been found in France, of procuring and preparing silk from the webs of spiders; and the using it in several manufactures has been attempted. This discovery is owing to M. Bon, in 1710, who published a dissertation on the subject, whence what follows is extracted.

Spiders are usually distinguished, either with regard to their colour, as into black, brown, yellow, white, &c. or with regard to the number, or arrangement, of their eyes; some having six, others eight, others ten. But with regard to the silk-spiders, M. Bon reduces them all to two kinds; those with long legs, and those with short: which last are those which furnish the finest raw silk. The silk-spider makes a silk every whit as beautiful, glossy, and strong, as the silk-worm: it spins it from the anus; around which are five papillæ, or small nipples; and behind these, two others, all muscular, and furnished with sphincters. These nipples serve as so many wire-drawing irons, to form and mould a viscous liquor, which, when dried in the air, after being drawn through them, makes the silk. Each of these nipples, M. Reaumur observes, consists of a number of less and insensible ones; which one may be convinced of by pressing a spider's belly between the fingers, to oblige the liquor to flow into the nipples; for by this means, applying the finger against the anus, several distinct threads will be drawn out through the several perforations of each nipple. The threads are too fine to be counted with any certainty; but M. Reaumur reckons each larger nipple may send forth a great many.

Hence we see how the spiders make their threads bigger or smaller: for as, before they begin to spin, they always apply more or fewer of these nipples against the body whence the web is begun; or, as they apply each more or less strongly; so, as more or fewer of the minuter nipples come to take, the thread thus spun will be a compound of more or fewer of the single threads. Indeed, as the threads come from the anus all joined together, they appear to be single; but M. Bon has distinguished one of the single ones to consist of fifteen or twenty distinct threads.

The threads are of two kinds: the first is weak, and only serves for that kind of web with which they catch flies. The second is much stronger, and serves to wrap up their eggs in; which, by this means, are sheltered from the cold, as well as from insects, which might otherwise gnaw and destroy them. These threads they wind very loosely round the eggs, resembling the balls or bags of silk-worms, that have been prepared and loosened for the distaff.

The spider-bags are of a grey colour, when new; but they turn blackish, when long exposed to the air: indeed, one might find other spiders' bags of other colours, and which would afford a better silk; but their scarcity would render the experiment difficult: for which reason, we confine ourselves to the bags of the most common spiders, which are the short-legged kind. These always find out some place, secure from the wind and rain, to make their bags; as hollow trees, the corners of windows, or vaults, or under the eaves of houses.

By collecting a quantity of these bags, a new silk is made, inferior in nothing to the common silk. It takes all kinds of dyes, and may be made into all kinds of stuffs. M. Bon had stockings and gloves made of it, which he presented to the Academy, and others to our Royal Society.

For the manner of preparing the bags to get the silk, it is thus: after having gathered twelve or thirteen ounces of these bags, M. Bon had them well beaten for some time, with the hand, and a stick, to get out all the dust; he then washed them in lukewarm water, till they left the water very clean: after this, he laid them to steep, in a large vessel, with soap, and saltpetre, and gum arabic. The whole was left to boil, over a gentle fire, for three hours. The bags were next washed in warm water, to get out the soap; and after all, laid to dry some days, to fit them

for carding; which was performed by the common silk-carders, but with cards much finer than ordinary. By this means, he had a silk, of a very particular ash-colour, which was easily spun; and the thread spun from it was both stronger and finer than that of common silk; which shews, that all sorts of works may be made of it: nor is there any reason to fear, but it will stand any trials of the loom, after having passed that of the stocking-weavers.

The only difficulty, now, is in procuring a sufficient quantity of spider-bags to make any considerable work of it; which, M. Bon observes, would be no difficulty at all, had we-but the art of breeding them, as we do silk-worms; for they multiply much more; every spider laying six or seven hundred eggs, whereas the silk-worms do not lay above one hundred; yet are these last so tender, &c. that one half die without making any bags, or are hindered, by some little accident, from making them; whereas the spiders hatch of themselves, without any care, in the months of August and September, in fifteen or sixteen days after they are laid; the old spiders that lay them dying soon after. The young ones thus bred live ten or twelve months without eating, and continue in their bags without growing, till the hot weather, putting their viscid juices in motion, induces them to come forth, spin, and run about to seek food. Were a method, therefore, found of breeding young spiders in rooms, they would doubtless, furnish a much greater quantity of bags than silk-worms do. For of seven or eight hundred young spiders, which M. Bon kept, hardly one died in a year; whereas of one hundred silk-worms, not forty lived to make their bags. M. Bon, having ordered all the short-legged spiders that could be found in the months of August and September to be brought to him, shut them up in paper coffins, and pots; covering the pots with papers, which he pricked full of pin-holes, as well as the coffins, to give them air. He fed them with flies, and found, some time afterwards, that the greatest part of them had made their bags. The same ingenious person found, that spiders' bags, with regard to their weight, afford much more silk than those of the silk-worms: as a proof of which, he observes, that thirteen ounces yield near four ounces of clear silk, two ounces of which will make a pair of stockings; whereas stockings of common silk weigh seven or eight ounces.

Nor is there any venom in the silk, or even in the spider, as many have imagined. M. Bon has been bit by them several times, without any manner of harm; and as for the silk, it is used with very good success to stop bleeding, and cure wounds, the natural gluten of it acting as a kind of balsam. It likewise yields, by distillation, several specific medicines, particularly great quantities of spirit, and volatile salt, which being prepared after the same manner as that drawn from the bags of silk-worms, in making the guttae Anglicanae, or English drops, at one time so famous all over Europe, may serve to make other drops of greater efficacy, which M. Bon calls drops of Montpellier, and advises to be used in all sleepy diseases.

M. Reaumur, being appointed by the Royal Academy to make a farther inquiry into this new silk work, has raised several objections and difficulties against it; which are found in the Memoirs of the Academy for the year 1710. The sum of what he has urged amounts to this. The natural fierceness of the spiders renders them unfit to be bred and be kept together: four or five thousand being distributed into cells, fifty in some, one or two hundred in others, the big ones soon killed and eat the less, so that, in a short time, there were scarcely left one or two in each cell; and to this

inclination of mutually eating one another. M. Reaumur attributes the scarcity of spider, considering the vast number of eggs they lay.

But this is not all: he even affirms, that the spider's bag is inferior to that of the silk-worm, both in lustre and strength; and that it produces less matter to be manufactured. The thread of the spider's web, he says, only bears a weight of two grains without breaking; and that of the bag bears thirty-six. The latter, therefore, in all probability, is eighteen times thicker than the former; yet it is weaker than that of the silk-worm, which bears a weight of two drachms and a half: so that five threads of the spider's bag must be put together, to equal one thread of the silk-worm's bag.

Now it is impossible these should be applied so justly over one another, as not to leave little vacant spaces between them, whence the light will not be reflected; and of consequence, a thread, thus compounded, must fall short of the lustre of a solid thread. Add to this, that the spider's thread cannot be wound off, as that of the silk-worm may, but must of necessity be carded; by which means, being torn in pieces, its evenness, which contributes much to its lustre, is destroyed. In effect, this want of lustre was taken notice of by M. de la Hire, when the stockings were presented to the Academy.

Again: spiders furnish much less silk than the worms: the largest bags of these latter weigh four grains; the smaller, three grains; so that 2304 worms produce a pound of silk. The spider-bags do not weigh above one grain; yet when cleared of their dust and filth, they lose two-thirds of their weight. The work of twelve spiders, therefore, only equals that of one silk-worm; and a pound of silk will require at least 27,648 spiders. But as the bags are wholly the work of the females, who spin them to deposit their eggs in, there must be kept 55,296 spiders to yield a pound of silk. Yet will this only hold of the best spiders; those large ones ordinarily seen in gardens, &c. scarcely yielding a twelfth part of the silk of the others: 280 of these, he shews, would not yield more than one silk-worm; 693,552 of them would scarcely yield a pound.

*SILK-Grass*, in *Botany*, a name used for two very different genera of plants, the aloe, and dog's bane.

*SILK-Tail*, or *Bohemian Chatterer*, in *Ornithology*. See *ROLLER*.

*SILK, Virginian*, in *Botany*. See *PERIFLOCA*.

*SILK-Worm*, *Bombyx*. This insect, which is a species of the phalæna, (see *BOMBYX*), consists of eleven rings, and each of these of a great number of other smaller ones, joined to each other; and the head, which terminates these rings, is furnished with two jaws, which work and cut the food, not by a perpendicular but a lateral action.

The humours found in the body of this creature all seem approaching to the nature of the silk which it spins; for on being rubbed in the hands, they leave a hard or solid crust behind them. Under the skin there is always found a mucous rosy-coloured membrane, enveloping the animal, and supposed to be the new skin in which it is to appear, on throwing off the old one. The heart of this creature reaches from the head to the tail, running the whole length of the body; it is, indeed, rather a series of many hearts connected together, than one: the motion of systole and diastole is very evident in this whole chain of hearts; and it is an elegant sight to observe the manner of the vital fluid's passing from one of them to the other. The stomach of this animal is as long as the heart, reaching, like it, from one end of the body to the other. This large receptacle for food, and the sud-

den passage of it through the animal, are very good reasons for its great voracity.

In the sides of the belly, all about the ventricle, there is deposited a vast number of vessels, which contain the silky juice: these run with various windings and meanders to the mouth, and are so disposed, that the creatures can discharge their contents at pleasure at the mouth; and according to the nature of the juices that they are supplied with, furnish different sorts of silk from them, all the fluid contents of these vessels hardening in the air into that sort of thread, of which we find the web or balls of this creature consist.

These creatures never are offended at any stench, of whatever kind; but they always feel a southern wind, and an extremely hot air always makes them sick. Malpighi de Bombyce.

SILKEBURG, in *Geography*, a town of Denmark, in North Jutland, with a castle, which was formerly very strong; 18 miles W. of Aarhus.

SILLA, in *Ancient Geography*, a river of India, which rose in a mountain of the same name, and lost itself in the ground, without receiving any other river.

SILLA, in *Geography*, a large town of Africa, in Bambarra, on the right bank of the Niger, within two short days' journey of Jenné, which is situated on an island in the river. This place was the boundary of Mr. Park's journey, and from hence he began his return homeward; 75 miles N.E. of Sego. N. lat.  $14^{\circ} 48'$ . W. long.  $1^{\circ} 34'$ .

SILLA Point, a cape on the north-west coast of the island of Mindanao. N. lat.  $9^{\circ}$ . E. long.  $123^{\circ} 51'$ .

SILLABAR, or CELLFEAR, a sea-port town on the west coast of the island of Sumatra, with a good and safe harbour; 30 miles S.S.E. of Bencoolen.

SILLAH-MEW, a handsome town of the Birman empire, situated on the Irawaddy. It is shaded by wide-spreading trees, and embellished with several temples. A smooth bank sloping to the river, and clothed with the finest verdure, adds much to its beauty. The soil around in general is but poor. Some fields are regularly fenced, and cattle in large herds graze in the neighbourhood.

SILLANGER, a town of Sweden, in Angermanland; 4 miles W. of Hernofand.

SILLANO, a town of Etruria; 8 miles S.S.E. of Volterra.

SILLEE, a circar of Bengal, bounded on the north by Rangur, on the east by Pachote, on the south by Tomar, and on the west by Nagpour; its form is square, and each side is about 16 miles.—Also, the capital of the above circar; 25 miles S.E. of Rangur. N. lat.  $23^{\circ} 22'$ . E. long.  $85^{\circ} 56'$ .

SILLEIS, in *Ancient Geography*, a river of the Troade.

SILLE-LE-GUILLAUME, in *Geography*, a town of France, in the department of the Sarthe, and chief place of a canton, in the district of Le Mans; 18 miles N. of Le Mans. The place contains 2121, and the canton 11,835 inhabitants, on a territory of  $247\frac{1}{2}$  kilometres, in 10 communes. N. lat.  $48^{\circ} 12'$ . W. long.  $0^{\circ} 3'$ .

SILLEWOOD, a small island in the North sea, near the coast of Norway; 30 miles N.N.W. of Bergen.

SILLINGA, a town of Bengal; 35 miles S. of Doesa.

SILLON, in *Fortification*, an elevation of earth, made in the middle of the moat, to fortify it, when too broad.

The fillon is more usually denominated an *envelope*.

SILLS, in *Agriculture*, a term signifying the shafts of a cart, waggon, &c.

SILLY, in *Geography*, a rock on the south coast of the island of Jersey; 2 miles S. of Noirmont Point.

SILLYUS, in *Ancient Geography*, a town of Asia Minor, in Ionia, in the vicinity of Smyrna.

SILM, or CILM MONOU, in *Geography*, a country of Africa, near the river Scherbro.

SILNO, a town of Lithuania; 4 miles N.N.W. of Grodno.

SILLO, in *Ancient Geography*. See SMILON.

SILLOE, SILOA, or Siloam, a fountain at the foot of the walls of Jerusalem, east, between the city and the brook Kidron, or Cedron. Josephus (De Bell. l. v. c. 26.) says, that when Nebuchadnezzar besieged Jerusalem, the waters of this fountain increased; and that the case was the same, when Titus besieged the city; so that, during the siege, it abundantly supplied the Roman army, and furnished also a sufficiency for watering the gardens; though, before this event, water could hardly be bought for money. The prophet Isaiah (ch. viii. 6.) insinuates, that its waters flowed gently and without noise. St. John speaks of the pool of Siloam. (John, ix. 7.) The tower of Siloam, mentioned Luke, xiii. 4. is thought to have been near the fountain.

SI-LONG, in *Geography*, a city of China, of the second rank, in Quang-si. N. lat.  $24^{\circ} 34'$ . E. long.  $105^{\circ} 18'$ .

SILLOOR, a town on the north-east coast of Sumatra. S. lat.  $1^{\circ} 8'$ . E. long.  $103^{\circ} 51'$ .

SILOXERUS, in *Botany*, so named by Labillardiere, from *συλος*, the *style*, and *συναξος*, *swelling*, on account of the tumid base of that part. It would have been difficult to trace this derivation, without authentic information from the author himself.—Labill. Nov. Holl. v. 2. 57.—Class and order, *Syngenesia Polygamia-fregata*. Nat. Ord. *Compositæ nucamentaceæ*, Linn. *Corymbifera*, Jussl.

Gen. Ch. *Common Calyx* scarcely any, except the leaves surrounding the common compound receptacle; *partial* inferior, of from five to seven equal, obovate-oblong, concave, membranous leaves, containing several florets. *Cor.* compound uniform, discoid, of from two to five tubular, monopetalous, regular, pitcher-shaped, five-toothed, perfect florets. *Stam.* Filaments in each floret five, very short; anthers linear, united into a tube. *Pist.* Germen in each floret inversely pyramidal, tuberculated; style awl-shaped, swelling very much at the base; stigmas two, obtuse, spreading. *Peric.* none, except the permanent partial calyx. *Seeds* solitary to each floret, inversely pyramidal, beset with rows of tubercles, and crowned with about twelve little teeth; down of one leaf, membranous, pellucid, in five ovate, acute, fringed lobes. *Common Receptacle* oblong, somewhat club-shaped, hairy, many-flowered; *partial* small, scaly, the scales membranous, oblong, scarcely longer than the florets.

Ess. Ch. *Common receptacle* hairy; *partial* chaffy. *Partial calyx* with from two to five perfect, equal, regular florets. *Seed-down* membranous, five-lobed, fringed.

1. *S. humifusus*. Labill. Nov. Holl. v. 2. 58. t. 209.—Native of Lewin's land, on the south coast of New Holland. A small, diffuse, herbaceous plant, with a tapering, apparently annual, root. *Stems* several, spreading, simple, leafy, an inch or two long. *Leaves* mostly opposite, simple, linear, obtuse, smooth, near an inch in length; several of them crowded under the heads of flowers, which are terminal, solitary, ovate or nearly globular, scarcely an inch long. Nothing is mentioned concerning the colour, scent, or properties of this little inconspicuous, but singular, plant.

SILPERRY, in *Geography*, a town of Bengal; 2 miles S.S.E. of Ghidore.

SILPHA,

## SILPHA.

**SILPHA**, in *Entomology*, a genus of insects of the order Coleoptera, of which the generic character is, Antennæ clavate, the club perfoliate; shells margined; head prominent; thorax somewhat flattened and margined. This genus of insects, from its habits, is known by the trivial name of the *Carrion-beetle*. The several species are commonly found among decayed animal or vegetable substances, frequenting also dung-hills, carrion, and other offensive matter: they lay their eggs chiefly in the dead and putrid carcases of animals. The larvæ are of a lengthened shape, and of an unpleasant appearance, being generally roughened with minute spines and protuberances. There are about 120 species, in eight separate divisions or sections. The following are most worthy of notice.

*Section A is characterized by a dilated and bifid Lip, and a one-toothed Jaw; in which, among others, are the following*

### Species.

**SURINAMENSIS.** Black; shells with a yellow band behind; hind-thighs toothed. It is found in South America.

\* **LITTORALIS.** This is a black insect; the shells are naked, with three raised lines; thorax rounded and polished. This is an European insect, and found in our own country.

**LIVIDA.** This is brown; thorax, shells, and legs livid. It is found in Germany.

**INDICA.** This, as its name imports, is an Indian insect; it is black; the shells are marked with two ferruginous bands; thorax one-toothed before.

**MICANS.** Black, with a green polish; shells striate, truncate, one-toothed. This is an inhabitant of the Cape of Good Hope. Tail rufous; shells black, with three elevated striz, one-toothed at the future.

**AMERICANA.** This, as its name shews, is found in divers parts of America. It is depressed and black; thorax is yellow and black in the centre. The shells are rugged and immaculate.

\* **THORACICA.** This is black; the shells are marked with a single elevated line; the thorax is testaceous. This and the following are English insects. According to Mr. Donovan's figure and description, the shells of this species have three raised lines. It is distinguishable by its red thorax, every other part being black.

\* **RUGOSA.** Blackish; the shells are ridged with three raised lines, the thorax is ridged and sinuate behind. This insect consumes dead carcases, fish, and flesh of all kinds: when caught it emits a very fetid humour.

\* **ASTRATA.** This is of a size similar to the thoracici, but is totally black, and has the wing-sheaths marked by three rising lines; its larva, which may be found in gardens, is of a lengthened shape, and of a black colour.

\* **LEVIGATA.** Black; shells smooth and sub-punctured. The shells are without raised lines.

\* **OBSCURA.** Black; the shells are punctured, with three raised lines; the thorax is truncate before. This species is figured by Donovan. The thorax has a blueish gloss.

\* **OPACA.** This is brown; the shells have three raised lines; the thorax is truncate before.

\* **SINUATA.** The thorax of this species is emarginate and rough; the shells have three raised lines, sinuate at the tip. This is a beautiful species; the thorax is brown, with a silvery gloss; it is rough, with raised dots.

\* **4-PUNCTATA.** The thorax is yellow, with a large black spot; the shells are yellow, with four black spots.

\* **GRISEA.** Grey; the shells are smooth; the thorax is emarginate.

*Section B is distinguished by an entirely rounded Lip, and a one-toothed Jaw.*

**4-MACULATA.** Thorax and shells black, the latter with two rufous spots; the body is rufous; the antennæ are ferruginous, brown before the tip, shells striate.

**MULTIPUNCTATA.** Rufous; shells substriate, with numerous rufous dots. This is found chiefly in Sweden.

**PICEA.** Pitchy; shells striate, black, the base and band behind are ferruginous. This is a very small insect, and is found in Germany.

**METALLICA.** This is of a brassy colour; the legs are ferruginous. It is found in divers parts of Saxony.

### C. Lip horny, entire; the Jaw is bifid.

**4-NOTATA.** Black; the shells are truncate, with two rufous spots. It is found in some parts of Germany. The antennæ are long; the five last joints are perfoliate; the shells are a little shorter than the body; the abdomen is acute.

**4-PUSTULOSA.** Black, polished; edge of the thorax and spots on the shells are sanguineous. It is found in New Holland; the shells are truncate, shorter than the abdomen.

**AGRICINA.** This also is black and polished; the antennæ and legs are yellow. It is found in many parts of Europe, but not in our own country. The shells are truncate, shorter than the abdomen; the body is black and immaculate; the abdomen pointed.

### D. Lip emarginate, conic; Jaw bifid.

**FASCIATA.** Black; the shells are marked with two rufous bands, the fore one spotted with black. It inhabits North America, and is a rather large insect; though less than the

**GRANDIS**, which is an African insect, and so named on account of its size. This is black, and the shells are marked with two rufous spots.

\* **4-PUSTULATA.** Black; the shells are marked with two ferruginous dots. This is found in England, and in many other parts of Europe. The larva is long, hairy, and grey.

\* **6-PUSTULATA.** Black; shells striate, with three rufous spots. This is found chiefly in the northern parts of Europe. It is reckoned a very beautiful species; the antennæ are pitchy; the thorax is ferruginous at the edge; spot at the base of the shells sinuate, the middle one is uniform; that at the tip is small and round; the body beneath is rufous.

\* **NIGRIPENNIS.** Rufous; the antennæ, shells, and breast are black. This is found chiefly on trees.

\* **RUFIPES.** This is a black insect; the head, thorax, and legs, are ferruginous. The abdomen is black.

\* **ÆNEA.** This is of a fine scarlet colour; the shells are brassy and immaculate.

\* **RUFIFRONS.** Black; but the front, two spots on the shells, and legs, are ferruginous. This is found in divers parts of England, and is reckoned a small insect.

*E. The Insects of this Section are characterized by a heart-shaped Lip, emarginate and crenate.*

\* **GERMANICA.** Black; front and edge of the shells are ferruginous. Sometimes the shells are marked with a ferruginous spot or two. It deposits its eggs in the carcases of other insects, and buries them under ground. It is very like the

\* **VESPILLO.** This insect, which is not uncommon in our own

own country, is the most remarkable of the European species. It is distinguished by having the wing-sheaths considerably shorter than the abdomen, or as if cut off at the tips; they are also marked by two wavy, orange-coloured transverse bars, the rest of the insect being black; the general length of the animal is about three-quarters of an inch. The vespillo seeks out some decaying animal substance in which it may deposit its eggs, and in order to their greater security, contrives to bury it under ground. Three or four of these insects, working in concert, have been known to drag under the surface the body of a mole in the space of an hour, so that not a trace of it has appeared above ground. The eggs are white, and of an oval shape: from these are hatched the larvæ, which, when full grown, are about an inch long, of a yellowish-white colour, with a scaly orange-coloured shield, or bar, across the middle of each division of the body. Each of these larvæ forms for itself an oval cell in the ground, in which it changes to a yellowish chrysalis, resembling that of a beetle; out of which, in the space of three weeks, proceeds the perfect insect. This species is reckoned very elegant in form, but it generally diffuses a very strong and unpleasant smell; it flies with strength and rapidity, and is usually seen on the wing during the hottest part of the day.

**MORTUORUM.** Black; shells marked with two ferruginous bands; the club of the antennæ is black; the hind-thighs are unarmed. This is found in many parts of Germany, preying on carcases and fungi.

#### F. *Lip square and emarginate.*

\* **SCARABÆOIDES.** Oval, black; the shells are marked with two ferruginous spots.

**LUNATA.** Oval, black; shells with a lunate yellow spot at the tip. It is about the size of the last, and is found in Germany.

**COLON.** Yellow; the spots on the thorax, and marginal spot on the shells, black. It is found in Sweden. The head is black; the antennæ are yellow; the club is black; the thorax is downy, with six spots disposed in a streak; the abdomen is black, edged with yellow.

\* **ATOMARIA.** This insect is smooth and black; the shells have crenate striæ; the legs are pale.

\* **MELANOCEPHALA.** This is black and smooth; the shells are grey, with a common black spot at the base.

\* **UNIPUNCTA.** This is black; shells yellowish, with a common black spot. The shells are sometimes immaculate.

\* **FIMETARIA.** Black, immaculate; the shells are very smooth. It is found chiefly in dung.

\* **MINUTA.** This is black and small; the shells are striate; legs of the same colour. It is found in many parts of England.

\* **PULICARIA.** This is oblong and black; the shells are abbreviated; the abdomen pointed. This is found chiefly among flowers.

G. *The Insects of this Section have a long and entire Lip; the Antennæ are serrate.*

\* **SAXICORNIS.** Smooth, polished, and of a chestnut colour; the antennæ are black.

**DEPRESSA.** Smooth, ferruginous; the shells are sub-striate, and the body is depressed. It is found under the bark of oak-trees.

#### H. *Lip and Jaw unknown.*

Of this section there are no English species; it will be sufficient to mention the following,

**INSIGNITA.** Black; shells obsoletely striate, with two large scarlet spots. Common at Berlin; as is the next.

**NIGRICANS.** Blackish; the shells are smooth, with four yellow spots.

**HISTEROIDES.** Black; the antennæ and legs are red; the shells are abbreviated with a red spot. It inhabits Upsal, and is the size of a louse.

**SILPHIUM,** in *Botany*, an old Latin name adopted from the Greeks, whose *σιλπίου*, according to the description in Dioscorides, is evidently one of the umbelliferous family, with a broad or flat seed. (See **LASER**.) Linnæus takes a great liberty, in transferring this name to a syngeneous genus, altogether American, in his *Corollarium Gen. Pl.* 16; nor does he, in his *Hortus Cliffortianus*, give any reason for this measure.—Linn. *Gen.* 444. Schreb. 580. Willd. *Sp. Pl.* v. 3. 2330. Mart. *Mill. Dict.* v. 4. Ait. *Hort. Kew.* v. 5. 163. Pursh 577. *Juss.* 118. Lamarek *Illustr. t.* 707. Gært. *t.* 171. (*Alteriscus*; *Dill. Elth.* 32. *t.* 47.)—Class and order, *Syngenesia Polygamia-necessaria.* *Nat. Ord. Compositæ oppositifoliæ*, Linn. *Corymbifera*, *Juss.*

**Gen. Ch.** *Common Calyx* ovate, imbricated, squarrose; its scales ovate-oblong, reflexed for about half their length, projecting on all sides, permanent. *Cor.* compound, radiant. Perfect florets in the disk several, of one petal, funnel-shaped, five-toothed; their tube scarcely more slender than the limb; female ones, in the radius, fewer, lanceolate, very long, often three-toothed. *Stam.* in the florets of the disk only, Filaments five, capillary, very short; anthers united into a cylindrical tube. *Pist.* in the florets of the disk imperfect, Germen thread-shaped, very slender; style thread-shaped, very long, villous; stigma simple: in the females, Germen inversely heart-shaped; style simple, short; stigmas two, bristle-shaped, the length of the style. *Peric.* none, except the unaltered calyx. *Seeds* in the disk none; in the radius solitary to each floret, somewhat membranous, inversely heart-shaped, with a membranous, two-horned, emarginate border. *Recept.* chaffy, with linear scales.

**Eff. Ch.** *Receptacle* chaffy. *Seeds* compressed, inversely heart-shaped, bordered; their down bordered, with two horns. *Calyx* squarrose.

Fifteen species are defined by authors, hardy herbaceous perennial plants, generally rather large, with the aspect of Sunflowers; their leaves opposite, whorled, or alternate; the flowers yellow. The horns of the seed are wanting in some of the species.

1. *S. laciniatum.* Jagged-leaved Silphium. Linn. *Sp. Pl.* 1301. Ait. n. 1. Pursh n. 1. Linn. *fil. fasc.* 1. 5. t. 3.—Stem hispid. Radical as well as stem-leaves pinnatifid; their segments deeply toothed.—On the banks of rivers, in the western territories of North America, particularly on the Mississippi, flowering from August to October. *Pursh.* Collinson sent the seeds to Linnæus. The stem is from eight to twelve feet high, simple, leafy, round, an inch thick, rough in the upper part with bristly hairs. *Leaves* alternate, stalked, two feet long, and one broad, with four or five remote lobes at each side; strongly ribbed, rough. *Flowers* four inches wide; the ten scales of their rough calyx armed with strong taper points.

2. *S. compositum.* Panicle Silphium. Michaux *Boreal-Amer.* v. 2. 145. Willd. n. 2. Pursh n. 2. (*S. laciniatum*; *Walt. Carol.* 217.)—"Stem smooth. Stem-leaves pinnatifid; radical ones ternate, with many segments. *Flowers* panicle."—In gravelly woods, near the sea-coast of Virginia and Carolina, flowering from August to October. Not above two feet high. *Flowers* small. *Pursh.*

## SILPHIUM.

3. *S. terebinthaceum*. Broad-leaved Silphium. Linn. Suppl. 383. Willd. n. 3. Ait. n. 2. Pursh n. 3. Jacq. Hort. Vind. v. 1. 16. t. 43.—Stem smooth. Radical leaves heart-shaped; those of the stem alternate, ovate, serrated, rough.—In Louisiana, and the western mountains of North America, flowering from August to October. *Pursh*. The stem is about five feet high, panicled at the top, with bright yellow, rather drooping, flowers, three inches in diameter. The radical leaves are a foot long, and nearly as broad, coriaceous, rough, sharply toothed, with very long footstalks.

4. *S. perfoliatum*. Square-stalked Silphium. Linn. Sp. Pl. 1301. Ait. n. 3. Pursh n. 4.—Leaves opposite, triangular, stalked, perfoliate. Stem square, smooth.—Native of the Allegany mountains, from Pennsylvania to Carolina, flowering from July to October, according to Mr. Pursh, who considers as a variety of this the *conjunctum*, Willd. Enum. 933. The present is a robust plant, frequent in large gardens or plantations, taller than a man. Leaves rough like a file, with bordered rough-edged footstalks, clasping the stem with their compound bases. Flowers about two inches wide, with a smooth calyx.

5. *S. connatum*. Round-stalked Perfoliate Silphium. Linn. Mant. 574. Willd. n. 5. Ait. n. 4. Pursh n. 5.—Stem round, hispid. Leaves opposite, distantly serrated, rough; combined at the base.—Found on the high mountains of Virginia and Carolina, flowering in August and September. Pursh, as well as Willdenow, justly insists on this being a very distinct species from the last, of which Michaux thought it a variety. The stem is round, covered in the upper part with deflexed bristly hairs. Upper leaves nearly entire, broad and perfoliate at the base. The flowers resemble those of the preceding.

6. *S. Aterifcus*. Hairy-stalked Silphium. Linn. Sp. Pl. 1302. Ait. n. 5. Pursh n. 6. (*Aterifcus coronæ folis folio et facie*; Dill. Elth. 42. t. 37.)—Stem round, hispid. Leaves opposite or alternate, oblong, acute, serrated, rough. Calyx fringed.—In mountain meadows of Virginia and Carolina, flowering from July to September. *Pursh*. Stem about two feet high, spotted with purple. Lower leaves alternate, coarsely toothed; upper nearly opposite, and more entire. Flowers nearly three inches broad.

7. *S. pumilum*. Dwarf Silphium. Michaux Boreali-Amer. v. 2. 146. Willd. n. 7. Pursh n. 7.—“Stem finely downy. Leaves oval, slightly serrated, obtuse, rather downy. Scales of the calyx obovate, obtuse. Seeds without horns.”—Gathered in Florida, by Bartram and Michaux. We have seen no specimen.

8. *S. integrifolium*. Entire-leaved Silphium. Michaux ibid. Willd. n. 8. Pursh n. 8.—“Stem quadrangular, harsh. Leaves opposite, sessile, oblong, entire, rough. Flowers on short stalks.”—On the most western of the Allegany and Illinois mountains, flowering from August to October. About four feet high. Leaves all uniform, erect; extremely rough on the upper side. Flowers few. *Pursh, Michaux*.

9. *S. levigatum*. Polished Silphium. Pursh n. 9.—“Stem simple, square, furrowed, smooth. Leaves opposite, sessile, ovate, pointed, minutely serrated, smooth on both sides; somewhat heart-shaped at the base. Scales of the calyx ovate, fringed.”—Gathered by Mr. Edlen, in Georgia, North America, about two feet high. Flowers densely corymbose. *Pursh*.

10. *S. trifoliatum*. Rough Three-leaved Silphium. Linn. Sp. Pl. 1302. Willd. n. 9. Ait. n. 6. Pursh n. 10. (*S. ternifolium*; Michaux Boreali-Amer. v. 2. 146.

*Chrysanthemum virginianum*, foliis asperis, tribus ad quatuor angulis, smooth. Leaves three in a whorl, ovato-lanceolate, rough, with unequal tooth-like serratures. Panicle three-forked.—On the high mountains of Virginia and Carolina, flowering in September and October. *Pursh*. Stem about six feet high, leafy, purplish, smooth to the touch. Leaves more or less accurately whorled, about three inches long and one broad, on short stalks; the floral ones entire. Flowers two inches in diameter. Calyx-seales broad, minutely fringed, smooth.

11. *S. ternatum*. Fringed Three-leaved Silphium. Willd. n. 10. Pursh n. 11.—“Stem cylindrical, smooth. Leaves three in a whorl, stalked, lanceolate, slightly and minutely toothed, roughish; fringed at the base: the upper ones scattered and sessile. Panicle forked. Calyx fringed.”—Retzius communicated to Willdenow a description of this, as a new species from North America, and Pursh saw a specimen in Mr. Lambert's possession. The stem is said to be four feet high. Lowest, as well as the uppermost, leaves scattered; those of the panicle sessile, two together. Calyx-seales in four rows. Florets of the radius broader than in the last; but those of the disk are shorter. *Retzius*.

12. *S. atro-purpureum*. Violet-stalked Silphium. Willd. n. 11. Pursh n. 12.—“Stem cylindrical, smooth. Leaves about four in a whorl, lanceolate, rough, nearly entire, almost sessile; fringed at the base: the upper ones scattered. Panicle forked.”—Willdenow was indebted to Retzius for this likewise, but Mr. Lyon is said to have met with it in Carolina and Georgia, flowering in August and September. Mr. Pursh, who had seen this plant alive, says it resembles the preceding, but is at first sight distinguished by the purple smooth stem. By the description of Retzius, the specimen of *S. trifoliatum* in the Linnæan herbarium should seem rather to belong to the present species. See its description above.

13. *S. tomentosum*. Downy Silphium. Pursh n. 13.—“Stem and footstalks downy. Branches single-flowered. Leaves alternate, heart-shaped, ovate, serrated, shaggy. Seeds without horns.”—Gathered in Georgia, by John Bartram, whole specimens are in Sir Joseph Banks's herbarium. *Pursh*.

14. *S. elatum*. Tall Silphium. Pursh n. 14.—“Leaves alternate, stalked, heart-shaped, sinuated. Calyx-seales obtuse.” Native of Carolina. *Herb. Banks*.

15. *S. reticulatum*. Reticulated Silphium. Pursh n. 15.—“Leaves alternate, ovato-lanceolate, heart-shaped, serrated, bluish, somewhat villous.”—Native of Florida. *Herb. Banks*.

*S. solidaginoides*, Linn. Sp. Pl. 1302, proves the same plant as *Rudbeckia oppositifolia*, Sp. Pl. 1280, under each of which names it lies in the Linnæan herbarium. It is also *Helianthus lewis*, Sp. Pl. 1278, adopted from Gronovius; and is Willdenow's *Buphthalmum helianthoides*, n. 19, to which last genus it had originally been referred by Lamarck in his *Hortus Upsulensis*. Finally this plant is now called *Helopsis lewis* in Pursh, p. 563, after Perfoon. See *Rudbeckia*.

*S. trilobatum*, Linn. Sp. Pl. 1302, is *Buphthalmum repens*, Willd. Sp. Pl. v. 3. 2233. n. 13. Lamarek Diet. v. 1. 515.

SILPHIUM, in Gardening, contains plants of the tall-growing, herbaceous, perennial kind, of which the species cultivated are, the jagged-leaved silphium (*S. laciniatum*); the broad-leaved silphium (*S. terebinthaceum*); the hairy-stalked silphium (*S. aterifcus*); and the three-leaved silphium (*S. trifoliatum*).

*Method of Culture.*—They are all readily increased by parting the roots, and planting them out in the autumn or spring, where they are to remain in the borders and clumps. They may also be raised by planting the slips in the same manner: they should be afterwards managed as the perennial sun-flower. They are durable in the root, but decay annually in the stalk.

They afford a good variety and effect among other perennial plants in the summer season, when put out in a proper manner.

**SILPHIUM**, in *Ancient Geography*, a country of Libya, which took its name from the plant. It commenced eastward towards Aziris and the isle of Platæa, and extended westward as far as the Syrtis.

**SILSTADT**, in *Geography*, a town of Germany, in the county of Wernigerode; 3 miles N.E. of Wernigerode.

**SILVA**, a river of Russia, which runs into the Kama, near the town of Silva, in the government of Perm.—Also, a river of Russia, which runs into the Tchufovaia, 16 miles N.E. of Perm.—Also, a town of Russia, in the government of Perm; 12 miles N.W. of Solikamsk.

**SILVA Piana**, a town of Switzerland, in the bishopric of Coire; 16 miles W.N.W. of Bormio.

**SILVANEZ**, a town of France, in the department of the Aveyron; 9 miles S. of St. Afrique.

**SILVELLA**, a town of Italy, in the department of the Upper Po; 3 miles E.N.E. of Cremona.

**SILVER**, a river of the King's county, Ireland, which rises on the north-west side of the Sliebh-Bloom mountains, and takes a northerly direction. It has this name in Beaufort's and Arrowsmith's maps, but is called the Frankford river by Mr. Longfield, in his report to the Bog commissioners, from the small town of Frankford, which it passes. Mr. Longfield represents it as capable of being easily made navigable for canal boats, and also of being made to contribute to the drainage of the vast bogs between which it flows. In one part of its course, a little before it joins the Brufna, the Macartney aqueduct, a part of the Grand Canal, passes over it.

**SILVER**, in the *Arts, Manufactures and Commerce*, and in *Domestic Economy*, is a white malleable metal, susceptible of a fine polish. In *Chemistry*, it is a simple inflammable body.

It is sometimes found in the native state, but more frequently combined with antimony, arsenic, or sulphur; forming the varieties of silver-ores; with which we shall begin, and then proceed to the assay and analysis, physical properties, and chemical properties of silver.

*Silver-ores* contain that metal either native, or alloyed with other metals, or mineralized by sulphur, and sometimes with the muriatic acid, the sulphuric acid, and in one rare instance with the carbonic acid.

Silver-ores principally occur in the rocks which have been denominated primary and transition rocks, and rarely in secondary rocks; but many rich argentiferous lead-ores occur in alpine lime stone and secondary strata. The ores of silver are accompanied by calcareous spar and sulphate of barytes, and sometimes with quartz, horn-stone, jasper, and fluor spar. It has been remarked, that the warmer regions of the globe afford the greatest quantity of gold, but the richest repositories of silver are situated either in high latitudes or in elevated regions. The most celebrated silver-mines of Europe are in Sweden and Norway, at no great distance from the polar regions; and those which are in warmer latitudes, are almost all situated near the summits of alpine mountains commonly covered with snow, as at Allemont in France, and the mines of Mexico and Peru, in

the centre of the Cordilleras. Silver never occurs, like gold, in alluvial soil, or the sands of rivers. After the mineralogical description of the ores, we shall give a short account of the principal repositories of silver at present known.

*Native silver, Argent natif* of Haüy, possesses the characters of silver extracted from other silver-ores, but is generally less malleable. The colour is pure white, but the surface is commonly tarnished, and is of a yellowish-brown or greyish-black. Native silver occurs crystallized in cubes and octohedrons; the crystals are small, and are often aggregated, forming beautiful ramifications; the branches sometimes cross each other in a rectangular direction, and are reticulated. It is sometimes in leaves and sometimes capillary, and when the filaments are much entangled, it becomes nearly compact. Native silver is also found in shapeless masses of considerable size. In the year 1750, there was found in the famous mine of Hemmels Furst, near Freyberg, in Saxony, a mass of native silver, which weighed one hundred weight and a quarter; in 1771 an equally large mass was found. It is also mentioned by Albin, in his "Meissnische Berg Arconicke," p. 30, "that at Schneeberg, in 1478, a rich silver vein was discovered; and so large a block of native silver cut out, that duke Albert of Saxony descended into the mine, and used this large block as a table to dine upon. It was smelted into four hundred centners of silver: a centner is 110 lbs." (Jamefon's Mineralogy.) Native silver is fusible into a globule, which is not altered by a continuance of the heat; it is scarcely ever pure: the metals with which it is alloyed are commonly gold, copper or arsenic, and iron. Native silver alloyed with gold is rare; its colour is intermediate between silver-white and brass-yellow; it often contains a considerable proportion of gold. The stones which form the matrix of native silver in the mine are very numerous; it sometimes appears to be infiltrated into the fissures, sometimes to vegetate on the surface, and in other instances to be intimately combined with the substance of the stone. It is found in almost all the silver-mines that are worked in Europe or America; but the masses discovered in America are not so large as some which have been found in Europe. The *pacos*, a most abundant ore in Peru and Mexico, consists of minute particles of native silver, intermixed with brown oxyd of iron; but the particles are too small to be seen without a lens, and bear but a very small proportion to the mass. Silver rarely occurs in detached grains, like gold or platina.

*Antimonial silver-ore* is composed of silver combined with antimony, without any other substance. Its colour is tin-white; it has a shining metallic lustre, which is often tarnished superficially reddish or yellowish. It is distinguished from native silver by its brittleness, being scarcely malleable: the structure is lamellar. It is commonly found crystallized in four-sided and six-sided prisms, having the sides deeply striated: its specific gravity is from 9.4 to 9.8. It melts easily before the blowpipe, giving a white smoke from the oxyd of antimony, and leaving a globule of silver. Its constituent parts are from .76 to .84 silver, and from 16 to 24 of antimony. Antimonial silver is rare, particularly the regular crystallizations of it. It occurs in veins with calcareous spar and sulphate of barytes, and is accompanied by galena and native silver. The foliated structure of antimonial silver distinguishes it from white cobalt-ore, which has a granular structure; it differs also from arsenical pyrites, both by its structure and softness; the latter is extremely hard. Antimonial silver yields to the knife.

*Arsenical silver-ore* is harder than the former species; its structure

# SILVER.

structure is less perfectly lamellar, the fracture more even, and the lustre weaker. It occurs in small, globular, and kidney-shaped masses; before the blowpipe it yields the smell of garlic, peculiar to arsenic; a globule of silver more or less pure remains. The constituent parts of this ore are given by Klaproth as under;

Silver	-	-	16
Arsenic	-	-	35
Iron	-	-	44
Antimony	-	-	4

Arsenical silver-ore usually occurs with native arsenic; dark red silver-ore, brittle silver-glance, lead-glance, and brown blende, in calcareous spar. It is a scarce mineral.

*Corneous silver-ore, or Horn-ore; Argent muriaté, Fr.* This mineral is distinguished by its translucency; it has a waxy or glistening lustre, is soft and tenacious, and yields to the nail. From these characters it is supposed to bear some resemblance to horn, whence its name. The most common colours of this mineral are pearl-grey, passing into greenish or reddish-blue or brown; it acquires a brownish tarnish. Horn-silver occurs crystallized in small cubes, and is sometimes, though rarely, acicular and capillary: it is more commonly in laminae or small masses, or forms a coating on native silver. It is fusible in the flame of a candle. Under the blowpipe, on charcoal, it yields a globule of silver, and gives out a disagreeable odour, from the escape of the muriatic acid. Its specific gravity is from 4.75 to 4.80. Horn silver-ore is accompanied with native silver, black silver-ore, brown oxyd of iron, quartz, and sulphate of barytes. It is supposed by some mineralogists to be the most recent formation of silver-ore. It occurs in veins in the silver-mines of Europe and America, and in Siberia, and is observed generally to occupy the upper part of the vein. According to Klaproth, it consists of 68 parts silver, 21 muriatic acid, a small quantity of sulphuric acid, with a portion of iron and earthy substances; but the latter may be considered as accidental. Horn-silver is rather a scarce mineral.

*Vitreous silver-ore; Silver-glance, or sulphuretted silver; Glaferz, Werner; Argent sulfuré, Häuy.* Its colour is a dark lead-grey; it is malleable, and may be cut with a knife; the surface, when cut, is shining, and has a metallic lustre; in its natural state it has often an iridescent tarnish. It occurs in a variety of forms, in branches, fibres, small irregular masses, and laminae, and is also frequently crystallized: the crystals are commonly the cube or octohedron, and the dodecahedron, with rhomboidal faces: the fracture is flatly conchoidal. The specific gravity of this ore is from 7.0 to 7.2: its constituent parts are from 73 to 85 silver, and from 15 to 25 of sulphur. When raised to a red heat, the sulphur is gradually sublimed, and the silver appears in filaments, dendritical or reticulated. Many mineralogists suppose that capillary native silver owes its formation very frequently to a similar kind of decomposition of vitreous silver-ore. This mineral occurs in veins, and is always accompanied with other ores of silver, and with galena, iron pyrites, brown blende, sulphate of barytes, calcareous spar, and quartz. It is found in almost all silver-mines in various parts of the globe.

*Brittle vitreous silver-ore; Shrod glaferz, Werner; Argent noir, Häuy;* differs from the former by its brittleness, splendour, and colour. The colour is intermediate between iron-black and dark lead-grey; it is brightly splendid externally; internally it alternates from shining to glistening; the lustre is metallic. It occurs massive and disseminated, and in thin small plates, and frequently crystallized in fixed prisms, variously terminated, and in rectangular four-

sided tables: the latter crystals frequently intersect each other, forming the cellular structure. The tabular crystals are generally minute. The fracture of the massive vitreous ore is uneven; that of the crystals imperfectly conchoidal. This ore is soft, brittle, and fusible by the blowpipe; the sulphur, arsenic, and antimony, are partly volatilized, and a globule of imperfectly malleable silver, accompanied with a brown scoria, remains. According to Klaproth, the brittle vitreous silver-ore, from a mine near Freyberg, contained

Silver	-	-	66.50
Sulphur	-	-	12
Antimony	-	-	10
Iron	-	-	5
Copper and arsenic	-	-	0.50
Earthy matter	-	-	1

*Black sulphuretted silver-ore; Silber schwarz, Werner;* differs from vitreous silver-ore by its want of lustre: it occurs massive, corroded, and in powder: the fracture of the former is uneven; the streak shining and metallic. It yields to the knife, and is fusible into a slag, containing globules of silver.

*Red silver-ore, or Ruby silver; Roth giltigerz, Werner; Argent rouge, and Argent antimonié sulfuré, Fr.* The colours of this mineral are various shades of red, passing from a bright-red to dark-red, and reddish-grey or black. When scraped, the powder is of a crimson colour. The crystallized varieties are translucent, or semi-transparent, and the transmitted light is a carmine, light blood, or cochineal-red. It occurs massive, disseminated, and in thin plates, and crystallized in hexahedral prisms, variously terminated, and in dodecahedrons, with triangular faces, nearly similar to the crystallization of calcareous spar, called dog-tooth spar. The primitive form of the crystal, according to Häuy, is an obtuse rhomboid, whose plane angles are  $104^{\circ} 28'$  and  $73^{\circ} 22'$ , and the inclination of the faces  $109^{\circ} 28'$  and  $70^{\circ} 32'$ . The fracture is usually uneven, and imperfectly conchoidal; its lustre externally is shining and metallic, internally glimmering, sometimes metallic. It is brittle, soft, yielding easily to the knife. Before the blowpipe it gives out a copious smoke, with an arsenical smell, and leaves a globule of silver. Its specific gravity is about 5.6. There are several minerals which have a red colour, and may at first sight be confounded with red silver, as the sulphuret of arsenic, or realgar; but this mineral becomes yellow when powdered. Cinnabar has a greater resemblance, but the specific gravity is 7, and it is entirely volatilized by the blowpipe. Red oxyd of copper has a specific gravity of 3.9, and is usually accompanied with native copper, malachite, and brown iron ochre; it also effervesces with nitric acid, and communicates to a solution of ammonia a blue colour. By these characters it may be known from red silver-ore. Werner has divided red silver-ore into two sub-species, the light and the dark. Klaproth analysed this mineral, and found it to contain only silver, sulphur, antimony, and oxygen. Proust has shown that there are two kinds of red silver-ore, the one containing arsenic, and the other antimony. The constituent parts, as given by Klaproth and Vauquelin, are

	Klaproth.	Vauquelin
Silver	60	54.27
Antimony	20.3	16.13
Sulphur	11.7	17.75
Oxygen	-	11.85
Sulphuric acid	8	-

## SILVER.

According to the analysis of Proust, a variety of this ore contained nearly .75 parts of metallic silver, and .25 of metallic arsenic. Red silver-ore occurs in veins, but is always intermixed with other minerals, particularly with compact galena, cobalt, sulphuret of arsenic, native arsenic, grey copper-ore, and sparry iron-ore; and has a matrix of calcareous spar, sulphate of barytes, fluor spar, or quartz. It is a common ore in silver-mines, both in Europe and America: the dark-red ore is considerably more productive than the light-red.

*Silver amalgam* consists of pure silver combined with mercury. It has been found in the silver-mine of Salberg, in the province of Dalecarlia, in Sweden, in the mines of Deux-Ponts, in the Palatinate, and in some other places, either in thin plates or grains, or crystallized into octohedrons and dodecahedrons. It is sometimes semi-fluid. Its colour is silvery-white or grey, the fracture conchoidal, and the lustre metallic. It is soft, breaks when cut, and whitens the surface of gold or of copper; when rubbed upon them warm before the blowpipe the mercury evaporates, and leaves the silver pure. The constituent parts, given by Klaproth, are

Silver	36
Mercury	64

*White silver-ore* has a near resemblance to compact galena. The colour is a light lead-grey, passing to steel-grey: it occurs massive and disseminated, and is generally intermixed with cubic galena. The fracture is most commonly even, but sometimes fine-grained and uneven, and also fibrous; the internal lustre is glitening and metallic; the streak shining. It is soft and brittle. The specific gravity is 5.3. Some mineralogists think this ore should be classed with the argentiferous ores of lead. According to Klaproth, different specimens from Hemmels Furt, near Freyberg, contain, of the

	Dark-white silver-ore.	Light-white silver-ore.
Lead	41	48
Silver	9.25	20.40
Antimony	21.50	7.88
Iron	1.75	2.25
Sulphur	22.0	12.25
Alumina	1.0	7

*Carbonate of Silver.*—This ore has hitherto been only discovered in the silver-mine of Winceslaus, in Swabia: it occurs sometimes in masses, and sometimes disseminated through other minerals. Its colour is a greyish-black; its fracture uneven, with a glitening metallic lustre; it is brittle and heavy, and effervesces with acids; it melts easily under the blowpipe. According to Mr. Selb, who first described this mineral, it contains

Silver	72.5
Carbonate of antimony	17.5
Carbonic acid	12

It contains also a slight trace of copper.

Besides the above ores of silver, there are ores of other metals which contain a portion of silver, and have been classed by some mineralogists with silver-ores. An argentiferous variety of grey copper-ore, of an iron-black or steel-grey colour, has received the name of black silver-ore. It occurs massive, disseminated and crystallized in tetrahedrons; the fracture is small conchoidal, with a shining metallic lustre; it is sectile and brittle. An ore which is a combination of lead, bismuth, and silver, has received the name

of bismuthic silver. Its colour is a light lead-grey: it occurs disseminated, but rarely ever in masses; the fracture is fine-grained, uneven, with a glitening metallic lustre; it is soft and rather brittle; before the blowpipe metallic globules appear on the addition of borax, which unite; the button is brittle, and of a tin-white colour: the flux acquires an amber colour. According to Klaproth this ore contains

Lead	33
Bismuth	27
Silver	15
Iron	4.3
Sulphur	16.3
Copper	0.9

Argentiferous lead-ores are common in Great Britain and in various parts of Europe. Many of these ores are not sufficiently rich to repay the expence of extracting the silver. It is procured in considerable quantities in North Wales, the north-west parts of Yorkshire, and in the counties of Durham and Northumberland. Indeed, many lead-ores in these counties contain a much larger portion of silver than the average proportion of that metal in the ores of Mexico and Peru; but mineralogists do not class them with silver-ores.

*Silver Mines in Great Britain.*—Silver-ores, properly so called, are of rare occurrence in our island. A few years since, a vein of silver was worked with great profit in the parish of Alva, in the county of Stirling, in Scotland. The ores were native silver, and vitreous silver-ore. From forty to fifty thousand pounds sterling value was extracted before the ore was exhausted, after which the search to recover the vein proved fruitless, and since that time no silver-mines have been worked in that country. The silver-ores at Alva were accompanied with copper, lead, and cobalt-ores, with a matrix of calcareous spar, and sulphate of barytes. It is supposed by Dr. Millar that the veins traverse rocks of argillaceous porphyry.

Cornwall and Devonshire yield the richest argentiferous lead-ores of any part of Great Britain; but the quantity of these ores is small. In the former county a small quantity of native silver, with other silver-ores, have been occasionally found. We have been favoured with the following account of the present state of the silver-mines in these counties from Mr. Mawe, author of Travels in Brazil, who visited them in the summer of 1815.

From the lead-mines of Ben-Alden, in Devonshire, a large quantity of silver has been extracted. The vein is situated in *killas*, (see SLATE,) and is filled chiefly with fluor spar and galena. It has been worked to the depth of 110 fathoms: the silver extracted from the north and south vein averages about 70 ounces to the ton of lead. Another vein, running in a more easterly and westerly direction, situated in the same *killas*, produces 170 ounces of silver in the ton of lead. The vein is worked under the river Tamar. These mines are of considerable importance; during the last six weeks, the silver extracted from the lead procured here exceeded six thousand ounces. The works are extensive, and laid to be well conducted.

About four miles to the south-east of Callington is a silver-mine of another description: the vein is situated in a similar rock of *killas* or chlorite slate. The vein was first worked for copper, but native silver and lead-ore were discovered in it. The mine is called Huel Jewel: the thickness of the vein rarely exceeds three or four inches. In many of the cavities were found a considerable quantity of capillary native silver, with galena, red silver-ore, and sulphuret of silver.

silver. The ores were exceedingly rich, and promised at one time an ample recompence to the adventurers.

The Hurland copper-mine, near Redruth, has produced a considerable quantity of native silver in a small vein, branching from the principal vein. Some of the fibres of silver were more than four inches long.

There is a lead-mine near Truro worked at this time, and a considerable quantity of silver is extracted from the lead, as it yields 100 ounces *per ton*.

Near Peranzabula, on the north coast of Cornwall, there was a mine formerly worked close to the sea, which produced lead-ores in various states, and a portion of horn-silver, fine specimens of which are in various cabinets. Mr. Mawe found some specimens of this rare mineral among the refuse of the mine.

At Comb-Martin, in North Devon, are some lead-mines, which were formerly celebrated for the silver, but at present they are not productive.

Argentiferous lead-ores are the common lead-ores of the northern counties and of Wales; they vary in the quantity of silver they contain, from a few ounces to 40, 60, or 80 ounces of silver *per ton*. Some few rare instances have occurred in the north-west part of Yorkshire, of their exceeding the latter amount. On the average, the argentiferous lead that is calcined to extract the silver does not contain 20 ounces *per ton*: by some it has been stated at 17 ounces.

According to Lehman, there are no known lead-ores in the world but what contain silver, except that of Villoch, in Carinthia. (Lehman sur les Mines.) But according to Dr. Watson, the quantity of silver necessary to defray the expence of extracting, and the loss of lead, was nine ounces *per ton*, when lead was at the price of 15*l.* *per ton*. The price of lead is now 26*l.* *per ton*, and though silver be also advanced, yet the difference in the relative prices of each, taking the above as a standard, is such, that to repay the expence of extraction, the lead should contain about fifteen ounces of silver in every ton.

It is not to be expected that the proprietor of any lead-mines rich in silver should be forward in declaring to the world the quantity of silver they contain. The proprietor of the lead-mine containing silver may indeed work the same without any apprehension of its being taken from him under the pretence of its being a royal mine; yet the crown, and persons claiming under it, have the right of pre-emption of all the ore which may be raised. There was an act of parliament passed in the sixth year of William and Mary, entitled, An act to prevent disputes and controversies concerning royal mines. This act declared, that every proprietor of a mine of copper, tin, iron, or lead, should continue in possession of the same, notwithstanding its being claimed as a royal mine, from its containing silver or gold; but it is further enacted, that the crown, or persons claiming under it, should have the privilege of purchasing all the ore which should be raised out of such mine, at the following prices, when made clean and merchantable: for copper-ore, at the rate of 16*l.* *per ton*; for tin-ore, except that of Devonshire and Cornwall, 40*s.*; for iron-ore, 40*s.*; and for lead-ore, 9*l.* The standard price then fixed, particularly for lead, was much higher than the ordinary price of the ore in which there was no silver. Owing to the existence of this act, it is probable that we are not acquainted with the quantity of silver at present extracted annually. We are informed, that the value of silver produced by the lead-mines of colonel Beaumont, in Northumberland and Durham, is not less than 4000*l.* sterling *per annum*; and other large proprietors also extract a considerable quantity of silver from the lead-ores in

the northern counties. At present we believe that there is no silver extracted from the Derbyshire lead-ores.

It appears from HOLLINGSHED'S Chronicle, that silver was formerly extracted from lead in various parts of the island. In the reign of Edward I. 1600 pounds weight of silver was obtained in the course of three years, from a mine in Devonshire, which had been discovered towards the beginning of his reign: this mine is called a silver-mine by the old writers, but it appears to have been a mine of lead that contained silver. The lead-mines in Cardiganshire have at different periods afforded great quantities of silver: sir Hugh Middleton is said to have cleared from them two thousand pounds *per month*, and to have been enabled thereby to undertake the great work of bringing the New River from Ware to London. The same mines yielded, in the time of Charles I. eighty ounces of silver in every ton of lead, and part of the king's army was paid with this silver, which was minted at Shrewsbury. Sir J. Pettie's Essay on Metal Works.

A mint for the coinage of Welsh silver had been previously established at Aberystwith; the indenture was granted to Thomas Bushel, for the coinage of half-crowns, shillings, sixpences, twopences, and pennies, and the monies were to be stamped with the ostrich feathers on both sides. In 1604 nearly 3000 ounces of this Welsh bullion were minted at one time at the Tower. Webster, in his History of Metals, published in 1671, makes mention, from his own knowledge, of two places in Craven, in the West Riding of Yorkshire, where formerly good argentiferous lead-ore had been procured. One of the places was Bronghite Moor, in the parish of Slaidburn; the ore held about the value of 67 pounds of silver in a ton: the other was at Skelkornfield, in the parish of Gilsburn; it had formerly belonged to a person of the name of Pudsey, who is supposed to have coined it, as there were many shillings in that country which the common people called Pudsey shillings. There are several smelting-houses at Holywell, in Flintshire, where silver is extracted from lead. According to Mr. Penant, at one of the largest of these houses in the year 1754, more than 12,000 ounces of silver were produced, but in the subsequent years the quantity of silver appears to have considerably diminished. The silver extracted from lead is sold principally to the manufacturers at Sheffield and Birmingham.

The silver is extracted from the lead by the oxydation of the latter metal in a reverberatory furnace of a particular construction, for the admission of air on the surface of the lead in a state of fusion.

A shallow vessel or cupel is filled with prepared fern-ashes rammed down, and a concavity cut out for the reception of the lead, with an opening on one side for the mouth of the bellows, through which the air is forcibly driven during the process. The French smelters cover the surface of the ashes with hay, and arrange symmetrically the pieces of lead upon it. When the fire is lighted, and the lead is in a state of fusion from the reverberation of the flame, the blast from the bellows is made to play forcibly on the surface, and in a short time a crust of yellow oxyd of lead, or litharge, is formed, and driven to the side of the cupel opposite to the mouth of the bellows, where a shallow side or aperture is made for it to pass over; another crust of litharge is formed and driven off, and this is repeated in succession till nearly all the lead has been converted into litharge and driven off. The operation continues about forty hours, when the complete separation of the lead is indicated by a brilliant lustre on the convex surface of the melted mass in the cupel, which is occasioned by the removal of the last crust of litharge that covered the silver. The French introduce water through a tube into the cupel, to cool the silver rapidly and prevent

its spirting out, which it does when the refrigeration is gradual, owing probably to its tendency to crystallize. In England the silver is left to cool in the cupel, and some inconvenience is caused by the spirting, which might be avoided by the former mode.

The silver thus extracted is not sufficiently pure; it is again refined in a reverberatory furnace, being placed in a cupel lined with bone-ashes and exposed to a greater heat: the lead which had escaped oxydation by the first process is converted into litharge, and absorbed by the ashes of the cupel.

The last portions of litharge in the first process are again refined for silver, of which it contains a part that was driven off with it. The litharge is converted into lead again, by heating it with charcoal; part is sometimes sold for a pigment, or converted into red lead. The loss of lead by this process differs considerably, according to the quality of the lead. The litharge commonly obtained from three tons of lead amounts to 58 hundred weight; but when it is again reduced to a metallic state it seldom contains more than 52 hundred weight of lead, the loss on three tons being about eight hundred weight. The Dutch are said to extract the silver from the same quantity of lead, with a loss of only six hundred weight.

*Silver-Mines of France*—The mine of Allemont, ten leagues from Grenoble, in the department of Isere, is situated near the summit of a mountain, composed of thin beds of mica-slate and hornblende, curiously contorted and broken. Its elevation is about 3000 yards above the level of the sea. The veins are numerous, and run in all directions: the mineral appears to have filled also numerous fissures in the rock. The ores are native silver, vitreous silver, red silver-ore, and horn-silver. Silver appears also disseminated in a kind of ferruginous clay, and is accompanied with various ores of cobalt, antimony, arsenic, and nickel. The matrix was ferruginous clay and carbonate of lime, mixed with albite, epidote, and calcareous spar. The veins were much richer near the surface than at a great depth, and the working of this remarkable mine is at present nearly abandoned. Red silver-ore has also been found in the Vosges, in the department of the Upper Rhine, in a vein of argentiferous copper-ore. Indications of silver have been traced in other districts of France. The lead-ores of some parts of France are also sufficiently rich in silver to repay the expence of extraction.

The *silver-mines of Spain* are the most ancient known in Europe. It appears, as well from the accounts of historians, as from the numerous vestiges of ancient workings, that the operations were carried on to a considerable extent. The most remarkable mine was that at Guadalquivir, in Andalusia, in the Sierra Morena, five leagues to the north of Seville; the ore which it contains is the red or ruby silver, in a matrix of compact galena. Since the discovery of South America no attention has been paid to the mines of Spain, though formerly so productive both of silver and gold.

*Germany*.—The mining district of Freyberg, in Saxony, contains numerous veins that yield silver. The veins that traverse rocks of gneiss are generally composed of quartz, calcareous spar, and fluor spar; they include argentiferous lead, vitreous silver-ores, ruby silver, and grey argentiferous copper-ore. The mine at Annaberg, according to Klaproth, contains muriate of silver (horn-ore) mixed with much clay, which is imbedded in compact lime-stone. The mines of Schneeberg, in Misnia, and of Hartz, in Hanover, contain argentiferous lead, accompanied with proper silver-ores.

*Hungary*.—The mines of Schemnitz and Kremnitz, in Hungary, have been long celebrated, both for the richness of their productions and the immense extent of the opera-

tions. The rocks in which the mining operations are carried on, are described as being composed of an argillaceous grey-stone, mixed with quartz or schorl, or particles of calcareous spar. To this rock baron Born has given the name of the metalliferous rock, *saxum metalliferum*: it is described by him as containing three principal veins, running from north to south, and parallel with the river Gran, following even the windings of the river. From this circumstance we should infer, that the river itself had originally taken the course of a fracture by another vein. The dip or inclination of all the veins is from west to east, varying from 30 to 70 degrees. In one part of the vein, called the *spitaler vein*, it is joined with an argillaceous white vein, which runs along with it on the *hanging side*, and from the place of junction the vein is found to contain silver. In this white clay are occasionally found nodules of spar and masses of quartz, which yield from four to five ounces of silver in the hundred weight. The second great vein at Schemnitz has nearly the same characters as the first. The third great vein is more irregular in its inclination, and the ores are not so rich in silver, but in some parts it contains a considerable quantity of gold.

Some notion may be formed of the extent of the mining operations at Schemnitz, from the gallery or level called the Emperor Francis' Gallery, by which the whole of the royal mine is drained and cleared of water. This gallery, which forms a very considerable excavation, and is carried through hard rock, was a work of immense labour and difficulty; it is five English miles in length: it was begun in 1748, and finished in 1765.

The mountains round Kremnitz, according to baron Born, are composed of the same metallic rock already described; but according to Patrin, they consist of primitive trap. At this place very extensive operations, which were begun at least a thousand years ago, have been established on a large and rich gold vein, and some of its branches. The rock is a white solid quartz, mixed with fine auriferous red and white silver-ore, and with auriferous pyrites. At the depth of 160 fathoms, the vein continued rich and productive.

Konigsberg is another mining-town of Hungary, some miles to the north-west of Schemnitz. The valley in which this place is situated is bounded on one side by the same kind of metallic rock, and on the other, towards the north, by granite mountains. In the royal mine, at the time it was visited by baron Born, the vein was observed to run between the metallic rock, which formed its *hanging side*, and the granite, which was its *hading* or lower side. The vein is grey quartz, mixed with auriferous pyrites. The first steam or fire-engine established in the Lower Hungarian mines was erected at Konigsberg, in 1725, by Isaac Porter, an English engineer, who was then in the imperial service.

*Bohemia*.—The circle of Saatz, in Bohemia, abounds in various metallic ores, among which the ores of silver occasionally predominate. The prevailing rocks are gneiss and argillaceous scistus. The veins at *Catharineberg* traverse gneiss, and generally run in a north and south direction, and parallel to the mountain in which they are situated. But there are also some powerful veins which cross the mountain. One of this nature is described, which seems to be insensibly blended with the mountain rock. The vein-stone is also of the same kind of rock, but occasionally assuming the characters of a variety of granite. It is observed, that the vein, which seldom exceeds a foot in width, diminishes in thickness when the containing rocks become harder; and when the sides are found incruited with a ferruginous clay, it appears to be richer in ores. Fissures from the sides of the vein are found to improve it: a fine white clay, with quartz

## SILVER.

quartz imbedded in it, indicates rich ore; but a coarse clay, destitute of quartz, especially when it increases in quantity, and occupies the whole vein, renders it unproductive, or entirely barren. The ores of the vein now described are rich silver and copper pyrites, with fluor spar, blende, various copper-ores, and sometimes native silver and copper.

*Joachimsthal*, a place in the same circle, has been long celebrated on account of its valuable mines. The prevailing rocks are described as grey micaceous and quartzose clay-slate, which at a great depth became more of an argillaceous nature, soft, foliated, and of a black colour. The mountains around this place have a gentle declivity towards the south, but run in lofty ridges to the east, north, and west, and are intersected by deep vallies. This inequality of surface affords great accommodation to the miners to open numerous galleries, which converge to the south, and to the valley in which stands the town of Joachimsthal. All the galleries and works of this district are divided into six different fields, belonging to the same number of companies, and they are drained by two deep drifts or levels; the one of which runs in a direct line 1600 fathoms; but including its several branches, its whole length is 4500 fathoms. The depth under the highest tops of the mountain is 170 fathoms: the second great level, which runs through the space of 5600 fathoms, and in a direct line 1500 fathoms, is 20 fathoms deeper than the first; but the operations in the mines have been carried to a much greater depth; for at the time in which they were visited by Ferber, before 1774, the perpendicular depth under the surface was from 200 to 350 fathoms, and, excepting the mines in the Tyrol, were then considered as the deepest in the world.

The thickness of the veins varies from one inch to two feet; and the vein-stones are a whitish or blueish clay, argillaceous slate, and reddish horn-stone, or petro-silex, which is the matrix of the richest ores. The silver-ores which are found in this mining district are, native silver, which is attached to different vein-stones, and assumes various forms; vitreous silver-ore, which is dug out sometimes in very large masses, and is considered as a very rich ore; one hundred weight being commonly valued at 180 marks of silver: red silver-ore, sometimes beautifully crystallized and transparent, is attached to red horn-stone or calcareous spar; and white silver-ore has sometimes but rarely appeared.

The silver-mines of *Bergstadt*, in the circle of Tabor, are in hills of a gentle declivity, and composed of grey or blueish clay-slate, in which appear figures of greenish lithomarge, or semi-indurated pot-stone. These mines were formerly rich in native silver, and other ores of that metal. A vein to the west of this place, which traversed a hard rock, contained reddish-coloured felspar, with galena, blende, and a little silver; but from the part where a vein containing white arsenical pyrites came into the hanging side, the vein produced native silver, vitreous, red, and white silver-ore. Another vein in the same place, which is from two inches to one foot in width, is observed to be richest where it is thinnest. It is chiefly enriched by an undulating black clay silure, which appears sometimes in the hanging side, and then it produces red and white silver-ore. When crossed by veins running from east to west, it appears to be cut off and barren, till beyond the place of junction it again becomes productive in its former course.

*Sweden*.—The silver-mines of Salberg, in Westmania, are about 28 English miles from Upsal. The ore is an argenticiferous galena, yielding from one marc to a marc and a half of silver *per* quintal; it is in compact lime-stone, and has been worked to the depth of 150 fathoms. The average profits

amount to about 400*l.* and one-eighth is paid to the king. Porter's Travels.

*Norway*.—The silver-mines of Konigsberg, in Norway, are situated in mountains of moderate height, composed of nearly vertical beds of mica-slate with garnets, and of grey quartz mixed with fine black mica, and a little lime-stone and red horn-stone. Other beds are composed of a ferruginous rock, which, in the upper part of the mine, is 33 feet thick, but in the lower not more than 6 feet thick.

The veins are from half an inch to two feet or more in thickness, and cut the strata transversely. The matrix of the ore is granular lime-stone, sometimes intermixed with fluor spar. Enormous masses of native silver have sometimes been found in this mine; one is mentioned as weighing 220 lbs. The common ores are native silver and vitreous silver. The veins are most productive in the ferruginous rock. The annual produce is about 5000 lbs. weight of silver.

*Asia*.—The silver-mines of Zmeof are situated in that part of the Altaian chain of mountains which lies between the Oby and Irtysh, from 50° to 52° north latitude. The annual produce has been stated at 60,000 mares of silver, which is alloyed with about 3 *per cent.* of gold. The mines of Nertschink in Daouria, near the river Amur, yield argenticiferous galena, producing about 30,000 mares of silver, and containing 1½ *per cent.* of gold. The Russian merchants who trade to China bring back ingots of silver, from several ounces to a pound weight, in exchange for their commodities; hence it may be inferred, says Patrin, that there are silver-mines on the frontiers of China. Patrin, Hist. des Mines.

*America*.—The most productive silver-mines in the world are those of South America and New Spain. Those of Peru, for many years after its conquest by the Spaniards, yielded the greatest quantity of silver; but at present the mines of Mexico are the richest. The mines of America furnish both silver and gold; and in making an estimate of their richness, we must take an account of each of these metals. The following table, given by M. Humboldt, will shew the distribution of these mineral treasures in the different parts of the new world; the kilogramme being 2 lbs. 3 oz. 5 dr. avoirdupois, or rather more than 2 lbs. 8 oz. troy.

	Gold.	Silver.
Viceroyalty of Peru	782	140,478
Viceroyalty of New Spain	1,609	537,512
Capitania of Chili	2,807	6,827
Viceroyalty of Buenos Ayres	506	110,764
Viceroyalty of Grenada	4,714	
Viceroyalty of Brazil	6,873	
Kilogrammes	17,291	995,581

The above was the annual produce of the different districts, at the beginning of the 19th century; from which it appears, that the total weight of the precious metals from all the mines in America, reduced to English pounds troy, is 45,580 lbs. of gold, and the enormous quantity of 145,000 lbs. of silver; equal in weight to one-third of the tin produced by the mines in Europe. Dr. Adam Smith, in his "Wealth of Nations," values the gold and silver annually exported into Cadiz and Lisbon at only six millions sterling, including not only the registered gold and silver, but that which may be supposed to be smuggled. This estimate is only two-fifths of the real annual amount.

The mountain of Potosi has furnished, since its discovery in 1545, a mass of silver equal in value to 234,093,84*l.* sterling.

## SILVER.

sterling. The mountain is 18 miles in circumference: it is composed of slate, but has a conical covering of porphyry, which gives it the form of a sugar-loaf, or basaltic hill; it rises 697 toises, or 480 yards, above the surrounding plain. The richness of the veins has diminished, as they have been worked to greater depths. At the surface of the earth, the veins of Rica, Centeno, and Mendicita, which traverse primitive slate, were filled with native silver, and silver-ores throughout their whole extent. These metallic masses rose in ridges or crests above the surface, the sides of the vein having been destroyed either by water or by some other cause. In 1545, minerals containing from 80 to 90 marcs of silver *per* quintal were common. In the year 1574, according to Acosta, the average richness of the ore was eight or nine marcs *per* quintal. In 1607, the mean wealth of the ores was not more than an ounce and a half to the quintal. The ores are now extremely poor, and it is on account of their abundance alone that the works are still in a flourishing state: for from 1574 to the year 1789, the mean quantity of silver in the ores has diminished in the proportion of 170 to 1; while the absolute quantity of silver extracted from the mines of Potosi has only diminished in the proportion of 4 to 1.

About six miles from Pasco is the mountain Jauvichora: it is distinguished by the name of the Silver mountain. It is about half a mile in diameter, and only about 30 yards in depth: it is composed of brown iron-stone, which is interspersed with pure silver. This stone does not yield more than nine marcs of silver in 500 lbs.; but there is a friable white clay met with in the middle of this mass of ore, which yields from 200 to 1000 marcs of silver in every 50 cwt. The mountain is penetrated in all directions, without any attention to security; so that it is expected it may fall in, in the course of a few years. According to Helms, this mountain yields annually 200,000 marcs of silver.

The veins of silver at Potosi are in slate, which Humboldt considers as primitive: this slate is covered with a clay porphyry, containing garnets. The mines of Gualgayoc, in Peru, are in the Alpine lime-stone. The veins which furnish nearly all the silver exported from Vera Cruz are in slate, porphyry, granwacke, and Alpine lime-stone: the principal of these veins are those of Guanaxto, Zacatecas, and Catorec. The vein of Guanaxto yields more than one-fourth of the silver of Mexico, and a sixth part of the total produce of America. This vein is, in some parts, from 147 to 150 feet in width, including the branches, and has been wrought from Santa Isabella and San Bruno to Buena-Vista, a length of 42,000 feet. The most celebrated mines in Mexico are elevated from 6000 to 9000 feet above the level of the sea. In the Andes, the mines of Potosi, Ocuero, Pas, Pasco, and Gualgayoc, are in regions higher than the loftiest summits of the Pyrenées. A mass of rich silver-ore has been discovered near the small town of Micuicampa, at the absolute height of 13,450 feet. The great elevation of the Mexican mines is peculiarly advantageous to the working of them, as the climate is temperate, and favourable to vegetation and cultivation.

The part of the Mexican mountains which at present contains the greatest quantity of silver, lies between the twenty-first and twenty-fourth degrees of latitude; and it is not a little remarkable, that the metallic wealth of Peru should be placed at an almost equal latitude, on the other side of the equator. In the vast extent which separates the mines of La Pas and Potosi from those of Mexico, there are no others which throw into circulation a great mass of the precious metals, but those of Pasco and Chota. The

isthmus of Panama and the mountains of Guatemala contain, for a length of 600 leagues, vast tracts of ground, in which no vein has hitherto been worked with success.

The province of Quito, and the eastern part of the kingdom of New Granada, from the eighth degree of south latitude to the seventh degree of north, are equally poor in metallic wealth. It would not, however, says Humboldt, be correct to infer that these countries, which have been convulsed and torn by volcanoes, are destitute of the precious metals. Numerous metallic repositories may be concealed by beds of basalt, and other rocks of supposed volcanic origin. It should, however, be remarked, that some of the rocks, which Humboldt enumerates as very metalliferous, are by other geologists considered of volcanic origin, particularly clink-stone-porphry, and other porphyries containing hornblende, but distinguished by the absence of quartz and common felspar.

The mines of Huantajaya are celebrated for the great quantities of native silver they formerly produced. They are situated in an arid desert, and surrounded by rock-falt, near the shores of the Pacific ocean, at no great distance from the small port of Yquique, in the audience of Lima. These mines are a remarkable exception to the great elevation of silver-mines in Spanish America, being placed on a low and gentle declivity. Their produce is native silver, vitreous silver, and horn silver; the annual amount is about 50,000 lbs. troy of silver, or 80,000 marcs.

The silver-mining operations of Chili, according to Humboldt, are in general not productive; but the vein at Uspalata contains *pacos* so rich, that the produce is from 2000 to 3000 marks in every 5000 lbs., or from 40 to 60 marcs *per* quintal. Molina, in his History of Chili, describes the vein at Uspalata, on the Andes, as being nine feet in thickness. It has been traced 90 miles, and is supposed to extend 300 miles. From the main vein there are branches on each side, which extend to the neighbouring mountains: some of these branches are 30 miles in length. This is the largest metallic vein which is at present known in the world.

According to Humboldt, the greatest part of the silver extracted from the bowels of the earth in Peru is furnished by a species of ore called the *pacos*, of an earthy appearance, which M. Klaproth analysed, and was found to consist of almost imperceptible particles of native silver with the brown oxyd of iron. In Mexico, on the contrary, the greatest quantity of silver annually brought into circulation is derived from vitreous silver-ore, grey silver-ore, horn-ore, and black and red silver-ores. Native silver is not extracted in sufficient quantity to form any considerable proportion of the total produce of the mines of New Spain. It is, says this traveller, a very common prejudice in Europe, that great masses of native silver are very common in the mines of Mexico and Peru, and that in general the mines of mineralized silver, destined to amalgamation, or to smelting, contain more ounces, or marcs of silver, to the quintal, than the silver-ores of Saxony or Hungary; but he adds, I was surpris'd to find that the number of poor mines greatly exceeds those of the mines which, in Europe, would be esteemed rich. It is at first difficult to conceive how the famous mine of Valenciana, in Mexico, can regularly supply 30,000 marcs of silver *per* month, as the vein consists of sulphuretted silver, disseminated in almost imperceptible particles through the matrix. In the formation of these veins, it should appear that the distribution of silver has been very unequal, being sometimes concentrated at one point, and at other times disseminated in the vein through the matrix or *gangue*; for, in the midst of the poorest ores

# SILVER.

are found considerable masses of native silver. Although the new continent has not hitherto produced single masses of native silver equal to what have been found in the old, the metal is more abundant in a state of perfect purity in Mexico and Peru than in any other quarter of the globe, not in masses, but in particles disseminated through the enormous quantity of the ore called *pacos*. The result of a general investigation of the richness of different mines is, that the mean richness of the different ores is not more than from three to four ounces of silver in every sixteen hundred pounds of ore. According to this result, the ore contains, on the average, two ounces and two-fifths *per* quintal. It had formerly been asserted, that no ores were worked in Mexico that did not contain one-third part of silver. The silver-ores of Peru are not richer on the average than those of Mexico. The district of Guanaxto has before been mentioned as furnishing more than one-fourth of the silver annually extracted in America, the riches of the mines here being superior to the celebrated repository at Potosi; they are all worked in one extensive vein. Among these mines, that of the count Valenciana is one of the richest; the average produce of silver is four ounces of silver from a quintal of ore.

The whole weight of silver from the vein of Guanaxto, on an annual average from 1786 to the year 1803, has been 556,000 marcs, or 364,911 lbs. troy; and in thirty-eight years the weight of gold and silver, from the same vein, has been 12,700,000 pounds troy. In average years it yields from 500,000 to 600,000 marcs of silver, and from 1500 to 1600 marcs of gold. It has been doubted by some persons whether this be really a vein, or a metallic bed, as in some parts of its course it is parallel between the beds, or strata of the rock. It passes through both slate and porphyry, and is metalliferous in both. Though it has been before stated that the extent of this vein is more than 42,000 feet; yet the enormous mass of silver which it has supplied for the last hundred years, sufficient alone to change the price of commodities in Europe, has been extracted from an extent of less than 2000 feet; for where this vein is not widened by branches, its general width may be stated at from 38 to 48 feet. It is for the most part separated into three masses, divided by banks of mineral matter, or by part of the matrix destitute of ore.

At Valenciana the vein continues undivided to the depth of 557 feet, and then divides into three branches; and its width, from the floor to the roof, is from 164 to 196 feet. Of these three branches of the vein, there is in general only one which is rich in metals. Sometimes, when these three branches unite, the mine is uncommonly rich. In this celebrated vein there is a certain middle region, which may be considered as a repository of greater riches, for above and below this region the ores are poor in silver.

At Valenciana the rich minerals have been in the greatest abundance, 300 and 1100 feet below the mouth of the gallery.

The labour of the miner is entirely free throughout the whole kingdom of Spain, and no Indian or Mexican can be fined to work in the mines. The Mexican miner gains from 1*l.* to 1*l.* 4*s.* sterling *per* week of six days. The men employed in agriculture do not gain more than a third of that sum. The miners work nearly naked, and are searched in the most indelicate manner on leaving the mine. They frequently conceal fragments of native silver and silver-ores in their hair, under their arm-pits, in their mouths, and even in the anus, into which they force cylinders of clay containing the metal. These cylinders are called *buganas*. A register is kept of the silver found in different parts of the

body. In the mine of Valenciana, the value of these stolen minerals, a great part enclosed in the longanas, amounted, from the year 1774 to 1787, to 30,000*l.* sterling.

The silver is extracted from its ores in New Spain by amalgamation with mercury, and by smelting: the proportion of silver extracted by mercury is  $3\frac{1}{2}$  to 1 of that extracted by smelting; and as fuel is becoming scarce, the quantity of silver extracted by amalgamation increases, the smelting being very imperfectly conducted.

The Mexican miners do not appear to follow any fixed principle in the selection of minerals destined to smelting or amalgamation; for in one district they smelt the same ores, which in another they believe can only be managed with mercury; and it is frequently the abundance or scarcity of mercury which determines the miner in the choice of his method. In general they smelt the argentiferous galena, and the mixed minerals of blende and vitreous copper. The *pacos*, the vitreous, red, and corneous silver-ores, the grey copper-ore rich in silver, and the meagre ores, disseminated in small quantities in the matrix, they find it more profitable to amalgamate.

All the metallic wealth of the Spanish colonies is in the hands of individuals. The government possesses no other mine than that of Huanca Velica in Peru, which has been long abandoned. The individual receives from the king a grant of a certain number of *measures*, on the direction of a vein or bed; and they are only held to pay very moderate duties on the minerals extracted. These duties have been valued on the average throughout all Spanish America at  $11\frac{1}{2}$  *per cent.* of the silver, and three *per cent.* for the gold. In the space of a hundred years, the annual produce of the Mexican mines has increased from twenty-five to one hundred and ten millions of francs. The produce of the mines in Peru has of late years been rather decreasing, which Humboldt attributes to its being worse governed than Mexico. The process of extraction seems also to be conducted upon worse principles than in New Spain, though in neither of these districts is smelting, or amalgamation, performed with much skill; for, according to M. Humboldt, the quantity of mercury annually consumed in New Spain exceeds two million one hundred thousand pounds troy. The mercury is separated from the amalgam by distillation; but in the whole process, the Mexicans waste eight times more than would be necessary, were the process conducted in the same manner as at Freyberg.

The following table will shew the annual produce of gold and silver in the mines of Europe, northern Asia, and America, as given by M. Humboldt, in kilogrammes. It may be regarded rather as an approximation to the real amount, than as a very accurate statement, the amount of English silver not being included; perhaps this may be estimated at 400 *lbs.* troy.

	Gold.	Silver.
Europe - -	1,297	52,670
Northern Asia - -	53 <sup>8</sup>	21,709
America - -	17,291	795,581

The kilogramme, it has been before stated, is rather more than 2 *lb.* 8 *oz.* troy. It is impossible to value the quantity of gold and silver annually extracted on the whole globe; for we are unacquainted with the amount of what is procured in the interior of Africa, and the central parts of Asia, Tonquin, China, and Japan. The quantity of gold and silver formerly brought by the Dutch from the latter country proves that it is rich in the precious metals. We may draw the same conclusion respecting the northern frontiers of China and other parts of Asia; and the quantity of gold-

# SILVER.

gold-dust brought to the western coast of Africa, leads us to believe, that the countries south of the Niger contain large quantities of this metal, though we have little information respecting the silver of the African continent.

*Assay and Analysis of Silver-Ores.*—Pure native silver requires no other alloy than fusion, with a little potash to free it from its earthy matter. In the humid way the silver may be dissolved in nitric acid, and precipitated by common salt. The precipitate may then be fused with soda in a crucible, by which the silver is obtained pure, and the muriate of soda sublimed. The auriferous silver-ores may be treated with potash, by fusion in a crucible: the alloy of silver and gold is first obtained, and the two metals may be separated by the process of parting. See REFINING and ASSAYING.

Those ores which consist of silver combined with antimony or arsenic, or both, are first roasted, to drive off the arsenic and antimony, the silver remaining pure. The process is much facilitated by the use of nitre, for the purpose of oxydating the metals to be dissipated.

The humid analysis of this ore requires more particular treatment.

The ore commonly called arsenical is first to be coarsely powdered, and then distilled vinegar poured upon it, to dissolve the lime of the calcareous spar adhering to it.

A given quantity of the ore so washed is now to be finely powdered, and nitric acid poured upon it: this oxydates the metals, dissolving the greatest part, and leaving a yellowish residuum. To the part dissolved muriate of soda is to be added, which precipitates the silver. This precipitate being washed and dried, will give 77 per cent. of pure silver. To the liquid from which the last was precipitated add a solution of potash; a lightish red precipitate is now formed, which, on drying, becomes of a deep brown, and by ignition assumes the form of powder of a whitish-grey colour: this is the arseniate of iron. This substance contains iron and arsenic, in the proportions of 50 to 43 or 44. This is shewn by treating the arseniate of iron with charcoal exposed to a red heat; the arsenic is reduced, and sublimed, while the black oxyd of iron remains.

The yellowish residuum left in the first solution is to be digested with muriatic acid: if a white powder remains undissolved, it will be found to be muriate of silver, and must be added to that first obtained. To the muriatic solution add a solution of carbonate of potash, and a yellowish-green precipitate is formed: to this precipitate, when washed and dried, add muriatic acid by a little at once, till the powder is dissolved; add a large quantity of water to this solution, which will produce a white precipitate; this being separated and dried will be pure oxyd of antimony, affording  $\frac{3}{4}$  of pure antimony. What remains in solution, after the last substance is separated by the water, may be precipitated by pure potash, and will be found to be oxyd of iron; which, when treated with charcoal, like the first obtained, may be added to the same to make the whole of the iron afforded by the mineral. In this way the arsenical silver-ore afforded, according to Klaproth, the following analysis:

Silver	-	-	12.75
Iron	-	-	44.25
Arsenic	-	-	35
Antimony	-	-	4
			<hr/>
			96
			<hr/>

The sulphuretted ores in the large way sometimes merely require to be roasted to drive off the sulphur: the heat being

urged affords a button of pure silver. This is the case with the variety called *Silver-glance*.

The brittle silver-ore contains a very small portion of antimony and copper. The metallic button obtained by heat will require to be cupelled with lead, in order to get the silver pure; it may, however, be made tolerably pure by treating the button with nitre, by which the base metals are separated.

To effect the humid analysis of brittle silver-ore, the powder is dissolved in dilute nitric acid with a gentle heat. By this treatment a residuum is left equal to  $\frac{2}{100}$  of the whole. The solution is to be treated with muriate of soda, like the last.

If the presence of an alkaline sulphate does not form any precipitate with the remaining solution, the mineral does not contain lead: add to the solution an excess of ammonia, and a greyish-white precipitate will be left, which is the oxyd of iron, often containing a little arsenic. If copper be present, ammonia will give to the remaining solution a fine blue colour, and that metal may be separated by a rod of clean iron.

It now remains to examine the first residuum which was unaffected by the nitric acid; this is to be digested with nitro-muriatic acid: the residuum left after this treatment will be found to be pure sulphur. The nitro-muriatic solution is now to be diluted with a large quantity of water; a white precipitate falls down, which, when washed, dried, and ignited, will be found to be oxyd of antimony, of a brown colour.

Klaproth found 100 grains of this ore to yield as follows:

Silver	-	-	-	-	66.5
Antimony	-	-	-	-	10
Iron	-	-	-	-	5
Sulphur	-	-	-	-	12
Copper and arsenic	-	-	-	-	.5
Extraneous matter from the mine	-	-	-	-	1
					<hr/>
					95
					<hr/>

The white silver-ores afford nearly the same ingredients with the last; and the mode of analysis will be similar in the dry way.

The *light-white* and *dark-white* silver-ores contain lead and alumine, and require a different treatment. After the iron is precipitated by common salt, a quantity of muriate of lead is formed at the time, which, on concentration, affords the muriate of lead in bright silky crystals. When these are collected till the liquid will afford no more, a solution of sulphate of soda is to be added, which precipitates the remainder of the lead in the state of sulphate of lead. This powder, being washed and dried, contains  $\frac{3}{4}$ ths its weight of metallic lead. The remaining liquid being supersaturated with ammonia, as in the analysis of the brittle silver-ore, a light-brown precipitate is formed: this precipitate is oxyd of iron and alumine. To separate the latter, dissolve the precipitate in nitric acid: separate the iron by prussiat of potash, or prussiat of lime, and afterwards the alumine with soda. The prussiat of iron, heated to a red heat, is decomposed, leaving the black oxyd of iron, which contains  $\frac{3}{4}$  of metallic iron.

The first residuum left by the nitric acid, besides antimony and sulphur, which constituted the residuum of the brittle silver-ore, also contains lead. By the frequent addition of muriatic acid with the application of heat, the lead is separated in crystals of muriate of lead; obtaining, by this means, a solution of the muriates of lead and antimony.

# SILVER.

mony. The residuum is sulphur. The muriatic solution deposits crystals of muriate of lead on cooling. When no more crystals fall down, these crystals are to be added to those obtained before. These, being heated in an assay crucible with twice their weight of black flux, afford metallic lead. This lead, however, treated in the usual way on the cupel, affords a small portion of silver. The solution still contains a small portion of muriate of lead and the antimony. By adding a solution of Glauber's salt, the lead is precipitated in the state of sulphate, affording  $\frac{2}{7}$ ths its weight of metallic lead. The antimony, which is the last, may be precipitated by affusion of water. The precipitate, being washed, dried, and ignited, is the pure oxyd of antimony, yielding on its reduction  $\frac{2}{7}$  of the metal. The analysis of the light white silver-ore, by Klapproth, gives of

Silver	-	-	-	-	20.4
Lead	-	-	-	-	48.06
Antimony	-	-	-	-	7.88
Iron	-	-	-	-	2.25
Sulphur	-	-	-	-	12.25
Alumine	-	-	-	-	7
Silex	-	-	-	-	0.25

					97.25

The corneous silver-ore, which is muriate of silver, is easily reduced in the dry way by fusing it with soda, in a crucible capable of fusing the metallic silver. The soda takes the muriatic acid, forming muriate of soda, which escapes in white fumes, and the silver is left pure.

In the humid way, it is first fused in a glass retort with carbonate of potash. The mass is then dissolved in hot water, and the solution filtered. The residuum is then dissolved in nitric acid, leaving behind a red powder. This powder, being treated with nitromuriatic acid, leaves behind a small portion of muriate of silver, which must be accounted for in metallic silver, as before directed. Ammonia, being added to the nitromuriatic solution, precipitates a red powder, which is oxyd of iron. To the nitric solution, from the mass first treated with carbonate of potash, muriate of soda is now to be added; which precipitates the silver in the form of muriate, from which the metallic silver may be either calculated, or obtained by fusion with soda. The aqueous solution from the fused mass is now to be saturated with acetic acid. If alumine be present, it will be precipitated. The liquid part is now to be evaporated to dryness. If alcohol be added to the dry mass, it dissolves the acetate of potash. The residuum is then dissolved in water. To this, muriate of barytes is to be added, which, if sulphuric acid be present, will cause a precipitation of sulphate of barytes, the sulphuric acid of which is to be considered as a product of the ore, and will be equal to one-third of the weight of this precipitate, when washed and dried. The remainder of the saline mass

which was dissolved in water may be considered as muriate of potash, the acid of which is another ingredient of the analysis, and will be equal to  $\frac{1}{7}$  of the salt.

*Physical and Chemical Properties of Silver.*—Silver, when pure and newly polished, is of a splendid white colour, and becomes more white when the polish is deadened. Its hardness is nearly that of copper. Its malleability is nearly equal to that of gold. At a heat visibly red in the dark it can be worked with great facility by the hammer into various articles, in the manner of working iron. After being rolled into very thin sheets, it can be beaten into leaves of  $\frac{1}{100000}$ th of an inch in thickness, and can be drawn into wire finer than a human hair. A wire of  $\frac{1}{17}$ th of an inch will require 336 lbs. to break it, when exerted in the direction of its length. At a temperature short of redness, these pieces can be united either by the hammer, or by pressing them together with friction by a steel burnisher.

It melts at the temperature of 28° of Wedgwood, or 4717° of Fahrenheit. If the heat be raised the metal becomes more liquid, and boils. This is occasioned by its assuming the elastic form, in which state it rises, and is condensable on the surface of bodies held over it, as has been observed with gold.

In purifying silver on the cupel, it is observed, that when it is removed from the furnace, and just at the point of congelation, a small explosion ensues, giving to the surface of the button an appearance as if some elastic fluid had been disengaged from it. It has been discovered by Mr. Samuel Lucas, of Sheffield, that the elastic fluid which is separated, producing the phenomenon in question, is pure oxygen gas.

By keeping silver long in a state of fusion, at a very high temperature, it becomes oxydated.

Macquer converted silver into a vitreous oxyd by exposing it to the heat of a porcelain furnace.

Silver is readily inflamed by electricity, and converted into an oxyd of a greenish-yellow colour.

The most direct way to obtain the oxyd of silver is by dissolving the silver in nitric acid, and precipitating it with lime-water. The precipitate is at first white, in which state it may be considered a hydrate of the oxyd. When heated, the water escapes, and it assumes a greenish-yellow colour, inclining to grey. If the heat be raised, the air being excluded, the oxygen is drawn off, leaving the metal in a state of purity: 100 parts of silver have been found to contain 7.5 of oxygen; hence, if the atom of hydrogen be 1, that of silver will be 100. No combination of silver with azote or carbon has as yet been discovered.

It combines with sulphur with great facility: the mere contact of the metal with flour of sulphur is sufficient to give the surface a yellow colour. If the silver be in thin plates, and stratified in a crucible with the same, at a red heat the combination soon takes place, and the mass fuses, forming a sulphuret of silver of a violet colour, sometimes in crystals of the shape of a needle.

This substance is brittle, but sufficiently soft to be cut with a knife. It is decomposable by heat. The sulphur escapes, leaving the metal in a state of purity. This compound is an atom of silver equal to 100, united to an atom of sulphur 15.

Sulphuret of silver is also formed by exposing the metal to sulphuretted hydrogen gas. The small quantity of the latter existing in the atmosphere is capable of soon communicating a yellow, and ultimately a purple colour to polished silver.

## SILVER.

Mr. Proust found this tarnishing matter to be a sulphuret of silver. The thinnest coat of gum, or of varnish, completely defends the surface of silver from tarnishing.

Silver combines with phosphorus, forming a phosphuret of silver. This combination is effected by heating in a crucible equal parts of silver and phosphoric glass, with one-fourth their weight of charcoal powder, or, what is better, saw-dust. This compound is of a white colour. It is brittle, but may be cut with a knife. It is, like the sulphuret, decomposable by heat.

Silver combines with several metals, forming alloys. The alloy of silver with gold, when the former is in a very small quantity, is of a much paler colour than gold. These, like all other compounds, are doubtless definite, and hence we should expect, that when these metals combine in the ratio of the weights of their atoms, which will be 100 silver to 140 of gold, the alloy would be the most perfect. And the next perfect would be two atoms of one to one of the other. It is stated by Muschenbroeck, that the hardest alloy of these two metals is with two parts of gold to one of silver.

Silver, as well as rendering gold much paler, gives it a greenish tinge. This alloy is more fusible than gold, and hence is employed as a solder for that metal.

Silver does not form any striking alloy with platinum. Indeed it rather appears to be a mixture than a combination. As is the case with lead and zinc, the two metals separate, when kept some time in a state of fusion. This fact is corroborated by the circumstance, that silver can scarcely be made to unite two pieces of platinum together, when used as a solder, while gold can be employed for that purpose with the greatest success. For the other alloys of silver, see the respective metals.

*Salts of Silver.*—These consist of the oxyd of silver combined with an acid, some of which only are soluble in water. The presence of the soluble salts of silver is easily detected by muriatic acid, or any soluble saline compound with that acid, by occasioning a dense white precipitate, which soon changes to a purple colour when exposed to the sun's light.

The insoluble salts of silver have the property of coating bright copper with silver, when rubbed upon it with a little moisture. Salts of mercury would give the same white appearance, but this would be distinguished from silver by being capable of dissipation by heat. Salts of silver become black with the hydro-sulphurets of the alkalies. And gallic acid gives a brown precipitate.

*Sulphate of Silver.*—Sulphuric acid has no action upon silver at the common temperature. When, however, this metal is boiled with the acid, the silver becomes oxydated, sulphurous acid gas is disengaged, and sulphate of silver is formed, which is a white mass, sparingly soluble in water, except an excess of sulphuric acid be present. The latter, on evaporation, affords crystals of a brilliant silvery whiteness, in the form of needles or fine prisms.

This salt is soluble in nitric acid.

When heated, it first fuses, and if the heat be raised, it is decomposed, sulphuric acid and oxygen escaping, leaving the silver in its metallic form.

This salt is decomposed by the alkalies and earths, and all those soluble salts, the acids of which form insoluble compounds with silver. Bergman has stated, that 100 parts of metallic silver, precipitated from nitric acid by sulphuric acid, give 134 of the sulphate. Allowing the 100 of silver to have taken 7 of oxygen, there will remain 28 for the sulphuric acid. This, in 100, will give sulphuric acid 22,

and 78 of oxyd of silver. If this salt be composed of one atom each of acid and base, then, by Dr. Wollaston's scale, the proportions would be 25.5 acid, and 74.5 oxyd of silver. Dalton's numbers would give very nearly the same result.

*Sulphate of Silver.*—This salt, like the last, is sparingly soluble in water. In other respects, it is but little known.

*Nitrate of Silver.*—The nitric acid acts with considerable violence on silver, affording red suffocating fumes, occasioned by the copious disengagement of nitric oxyd. If the acid and the silver be pure, the solution becomes clear and colourless, without residuum: if the acid contains muriatic acid, which is often the case with the acid of the shops, then a dense white powder will fall down, which becomes purple in the sun-shine, and is the muriate of silver: if the silver contains gold, a purple powder will be left at the bottom of the vessel: if it contains copper, the solution will be of a green colour, of greater or less intensity, depending upon the quantity of that metal.

The solution of silver affords crystals on evaporation: they are of a prismatic form, but differ in their number of sides; they do not change by exposure to the air, but are very soluble in water. These crystals, when heated, first melt; the heat being raised, the water of crystallization escapes, but the mass still remains liquid: in this state it is frequently cast into moulds, in which it assumes a solid form on cooling. These sticks, which are employed in surgery under the name of *lunar caustic*, are of a grey colour, and when broken exhibit a crystalline appearance.

A more violent heat than that required for its fusion decomposes it, nitrous gas and oxygen being disengaged.

This decomposition is much more rapid when it is heated in contact with inflammable matter. If thrown upon burning coals, it detonates.

If silk, cotton, leather, ivory, and many other bodies, be moistened with nitrate of silver, and the part be afterwards moistened, when a stream of hydrogen gas is applied to it the silver becomes reduced, and appears with its metallic lustre. A stick of phosphorus dipped in nitrate of silver soon becomes coated with metallic silver.

This salt has the property of detonating with sulphur or phosphorus, by being struck smartly with a hammer.

Nitrate of silver is decomposed by all the earths which form salts, and by the alkalies, by combining with the acid. Ammonia, however, does not only precipitate the oxyd, but afterwards combines with it, forming a compound having alarming fulminating properties. The following is the process recommended for its preparation.

From the nitrate of silver precipitate the oxyd by means of lime-water: separate the oxyd, and dry it upon blotting-paper: upon this oxyd pour pure caustic ammonia: let this remain for twelve hours. If a pellicle be formed upon the surface, add a little more ammonia, which will take it up. A black precipitate will be found at the bottom of the vessel, which is the ammoniate of silver, and is the fulminating substance to be obtained. This precipitate is to be carefully collected, and laid in very small quantities upon separate bits of blotting-paper, to dry. When dry, the slightest touch or rubbing motion causes a violent explosion. Those unaccustomed to it should begin with the smallest possible quantities, as serious accidents have happened by exploding it in too large quantities. The liquid part from which the substance was separated will be found to be a solution of the same: if it be heated in a glass retort, a portion of it is decomposed, and the gaseous products disengaged: in a little time, small brilliant crystals of the same substance appear: these

# SILVER.

these frequently detonate with such violence, as to break the vessel in which they are contained.

The theory of these appearances is obvious: the oxygen of the silver combines with the hydrogen of the ammonia, forming water, which, with the azotic gas of the fame, are in an instant rendered so highly elastic by the caloric set free, as to produce the explosive effect so conspicuous in this substance. It is needless to say that the silver is left in the metallic form.

Nitrate of silver is decomposed by all those metals having a superior attraction for oxygen. The oxygen of the silver is given to the decomposing metal, which also combines with the acid. Copper, so employed, precipitates the silver in a white metallic powder, the result being nitrate of copper in the place of nitrate of silver. The precipitate is not pure silver, some copper will always be detected when the precipitate is re-dissolved.

Mercury has also the property of precipitating silver from the nitrate, producing the appearance which has been termed the *arbor Diane*. Lemery recommends one part of silver to be dissolved in nitric acid, and the solution to be then diluted with twenty parts of distilled water: to this add two parts of mercury. The mercury gradually occupies the place of the silver, and the latter is precipitated in the form of vegetation, from which the name has been derived.

The vegetative appearance is caused by the growth of the crystals being from the extreme points of that already formed, as is the case with the growth of vegetables. The mercury, and the smallest portion of precipitated silver, form a Galvanic combination. The silver now in solution is reduced upon that already formed, in consequence of its state of electricity being negative, that of the mercury being relatively positive, by which it attracts the acid. This process would doubtless be facilitated by dropping a small bit of metallic silver upon the mercury, added to nitrate of silver. This would form a Galvanic combination, and the bit of silver would become an immediate rallying point for the silver in solution. If a little of a dilute solution of nitrate of silver be spread upon a pane of glass laid in an horizontal position, and a common pin be laid in the middle of the covered part, in a few hours, beautiful ramifications of silver extend from every side of the pin; sometimes to the distance of an inch. This is also to be explained by Galvanism.

*Muriate of Silver.*—When muriatic acid, or any soluble muriate, is added to nitrate of silver, a dense and blueish-white precipitate is thrown down, which is muriate of silver. Although white when it is just precipitated, it soon assumes a purple tint by exposure to the light, and the change is quicker as the light is more intense: hence this substance has been employed to measure the degree of intensity of light, by the time in which the change of colour takes place.

It may be said to be insoluble in water: this property, and its conspicuous appearance in other respects, renders the nitrate or sulphate of silver so valuable as a test for muriatic acid. The latter, on combining with the silver, forms the salt in question.

When this salt is exposed to heat, it easily melts: on cooling, it becomes solid. It is a semi-transparent mass, of a grey colour, and of a horny appearance, from which it has been called *luna cornea*, or horn-silver. If fused with a great heat in a crucible, it becomes so thin a fluid as to sink through the pores of the crucible. It is not decomposed by any of the acids nor the alkalis, but when heated with the carbonates of potash or soda, the acid is disengaged. It dissolves in caustic ammonia, forming a transparent solution: this, by exposure to the air, undergoes considerable change. A pellicle forms on the surface, which is first of a blueish colour,

and ultimately black. This pellicle, on examination, is found to be muriate of ammonia and reduced silver. Those who with Sir Humphrey Davy hold oxymuriatic acid to be a simple body under the name of chlorine, consider this substance as a compound of the latter substance with metallic silver. Sir Humphrey gives it the name of *argentane*, and Dr. Thomson, more consistently, *chloride of silver*.

The composition of this salt, according to Proust, is:

Muriatic acid	-	18
Oxyd of silver	-	82
		100

By the atonic theory it should be constituted by 100 + 7.5 = 107.5 of oxyd of silver, and 24 muriatic acid, which would give

Oxyd of silver	-	81.7
Muriatic acid	-	18.3
		100

Sir Humphrey considers it as a compound of one proportion of chlorine, 67, and one proportion of silver, 205, which will give

Silver	-	75.3
Chlorine	-	24.7
		100

Considering the 24.7 of chlorine as oxymuriatic acid, which would be 18.8 muriatic acid, and 5.9 oxygen; then giving this oxygen to 75.3 of silver, would give 81.2 of oxyd of silver, and 18.8 of muriatic acid in the 100, which nearly agrees with the above. The property which this salt has of becoming black by the action of light, has rendered it useful for marking linen. Very improper ingredients have been fold for this purpose. The nitrate of silver is employed to write with upon the linen, which is very proper; but the part is often prepared by a solution of soda or potash, instead of a solution of muriate of soda (common salt). The following will be a recipe which cannot fail of success: dissolve 30 grains of lunar caustic in one ounce of distilled water; this will be for the writing liquid. For the preparing liquor, dissolve half an ounce of common salt in four ounces of water; and in the same dissolve half an ounce of gum arabic. Moisten the part to be marked with the latter, and dry it till the writing will not run. The letters will first appear of a blueish-white, but become perfectly black by exposure to light.

The fluete, borate, phosphite, carbonate, and arseniate of silver, are insoluble powders, having no striking properties, or but little known. The arseniate is formed by adding arseniate of potash to any soluble salt of silver. It falls down in the form of powder of a yellow colour. Its insolubility, and its conspicuous colour, have been taken advantage of by employing nitrate of silver as a test for arsenic.

The chromate of silver is an insoluble salt, of a red colour: it is formed by adding chromate of potash to nitrate of silver. It, however, becomes purple by exposure to air and light.

Acetate of silver is a soluble salt, formed by adding the acetic acid to oxyd of silver. The solution affords prismatic crystals.

The rest of the salts are but little known.

SILVER, in *Medicine*, is called *luna*, the moon; and has been much extolled for its virtues by chemical writers. But

crude silver, however comminuted or attenuated, has not been observed to produce any medical effect. It is not soluble in any of the fluids of the animal or vegetable kingdom.

Several preparations have been made from silver; particularly a

**SILVER Pill**, or *Pilula Lunaris*, which is a chemical preparation of silver, formerly highly commended as an anthelmintic, and as a purgative remedy for dropsies, and in many other inveterate ulcerous diseases.

The method of making it is this: dissolve an ounce of pure nitre in distilled water; then dissolve an ounce of crystals of silver, made in the common way, with pure silver and aqua fortis, in three times the weight of water, so that the solution may be perfectly limpid: mix the two solutions together, they will become a clear homogeneous liquor; evaporate this to a pellicle, and crystals resembling nitre will shoot; pour off the remaining nitre as before, and the remaining nitre will shoot with the silver, in form of crystals, again, upon a second evaporation: let these crystals be dried upon a paper, and then placed in a glass vessel in a very gentle heat, enough to make them smoke, but not run; stir it with a piece of glass all the time, and keep it over the fire, till no more fumes arise; thus the acid spirits will be driven off, and the silver remain of a very bitter taste and purging quality. It must be kept in a dry close vessel.

This discovery has been made to serve to many other purposes, besides its uses in medicine, and has furnished the dishonest pretenders to alchemy with one of their most cunning methods of deceit. They have been able, by this means, to conceal silver in nitre, and that in a very large proportion, as in one-tenth part of the whole quantity; and this nitre being projected in an equal quantity on melted lead, gives an increase of one-tenth part in silver, which remaining upon the test, will deceive the ignorant, as if a tenth part of the lead were converted into pure silver. People who are upon their guard, may, however, discover the cheat, by dissolving the pretended nitre in ten times its weight of water, and putting a polished plate of copper into the solution; for every particle of the silver will then be precipitated out of the liquor upon the copper, and to the bottom of the vessel.

The medicinal use is this: the dried mass, consisting of the salts of silver and nitre, is to be reduced to a fine powder: this powder, applied to ulcers, acts in the manner of the lapis infernalis, or silver-caustic, only much milder: but for internal use, the quantity of two grains of it is to be ground to a fine powder, with six grains of loaf-sugar, in a glass mortar; this is to be then mixed with ten grains of the crumb of bread, and formed into nine pills: these are to be taken by a grown person upon an empty stomach, drinking after them four or six ounces of hot water, sweetened with honey. It purges gently, and brings away a liquid matter like water, often unperceived by the patient. It is said to kill worms, and perform great things in many obstinate ulcerous disorders. It purges without griping, but it must not be used too freely, nor in too large a dose, for it always proves weakening, and in some degree corrosive on the stomach; but this inconvenience is greatly alleviated by rob of juniper. Boerh. Chem. part ii. p. 297.

However, with this assistance, it is at best a dangerous medicine, and as such is deservedly excluded from practice. Lewis.

**SILVER, Tincture of**, is made by dissolving thin silver plates, or silver shot, in spirit of nitre; and pouring the solution into another vessel full of salt-water. By this means, the silver is immediately precipitated in a very white

powder, which they wash several times in spring water. This powder they put into a matras; and pour rectified spirit of wine, and volatile salt of urine, upon it. The whole is left to digest in a moderate heat for fifteen days; during which, the spirit of wine assumes a beautiful sky-blue colour, and becomes an ingredient in several medicines. This is also called *potable silver*, *argentum potabile*.

Silver is likewise converted into crystals, by means of the same spirit of nitre; and this is called *vitriol of silver*.

The lapis infernalis argenteus is nothing but the crystals of silver melted with a gentle heat in a crucible; and then poured into iron moulds. See **CAUSTIC**, *Lunar*.

**SILVER Ale**. See **ALE**.

**SILVER Bulb**, in *Botany*, a species of *Anthyllis*; which see. See also **BARBA Jovis**.

**SILVER Coin**. See **COIN**, and **MONEY**.

**SILVER Fir**, the name of a tree of the pine kind. See **PINE**.

**SILVER, Green and Herring**. See the adjectives.

**SILVER, Inflammable**, a chemical preparation of the lapis infernalis made by a small heat. The process is this: take an ignited piece of Dutch turf, after it ceases to smoke; place it with its upper flat surface parallel to the horizon; make a little cavity in the middle, and therein put a drachm of dry lapis infernalis; it will immediately melt and glow, and finally it will take flame, and hiss and shine like nitre: after the flame ceases, pure silver will be found in the hollow, as much in quantity as was used in making so much lapis infernalis.

This curious experiment shews the physical manner in which acids do but superficially adhere to silver; and the manner in which acids operate, when united to metals, while surrounding their metallic mass, they arm the ponderous principles of them with spiculæ: it shews also the immutability of silver dissolved in an acid, and the various ways in which it may be concealed, yet still have its action: it also shews the difference of potable silver, while existing in a saline form, by means of an adhering acid, from that potable silver of the adepts, where the principles of silver are supposed converted into a fluid, that will mix with the juices of the body, and cannot be reduced to silver again; but the great thing to be here observed is, that the acid spirit of nitre, adhering in a solid mass of silver, is, in this state, as inflammable, on coming in contact with an ignited combustible body, as crude nitre itself: this seems to happen with silver alone, which is unchangeable with spirit of nitre. Hence also we see one way, by which silver may be obtained pure from other adhering matters, by bare burning: the acid here acts neither upon the mercurial part of the silver, nor on its fixing sulphur. Boerh. Chem. part ii. p. 297.

**SILVER, King's**. See **KING'S Silver**.

**SILVER-Leaf** is that which the gold-beaters have reduced into fine thin leaves, to be used by gilders, &c. See **GOLD-Leaf**.

**SILVER, Quick**. See **MERCURY**.

**SILVER, Rep**. See **REP Silver**.

**SILVER, Salt**. See **SALT Silver**.

**SILVER, Shell**, is made of the shreds of silver leaves, or of the leaves themselves: and used in painting and silvering certain works. It is prepared after the same manner as shell-gold. See **GOLD**.

**SILVER, Slough**. See **SLOUGH Silver**.

**SILVER, Smoke**. See **SMOKE Silver**.

**SILVER-Tree**, in *Botany*. See **PROTEA**.

**SILVER-Weed**, a species of *Potentilla*; which see.

**SILVER-Weed**, in *Agriculture*, a term applied to wild tansey; a plant which grows naturally upon cold stiff land

in most parts, and is a sure mark of the sterility of the soil. Its stalks spread upon the ground, and send out roots from their joints; by which means, and by frequent shedding of its seeds, as it flowers during the whole summer, it soon over-runs, and fills the land to a great distance. Its leaves are composed of several lobes or wings, which are generally placed along the mid-rib, and terminated by an odd one: they are jagged at their edges, and are of a silvery colour, especially on their under side. It has been noticed by Mr. Ray, that the root is somewhat of the tap-rooted or parsnip kind, and that hogs are very fond of feeding upon it.

SILVER, *White-hart*. See WHITE-HART *Silver*.

SILVER *Wire*, is silver drawn through the holes of a wire-drawing iron, and by this means reduced to the fineness of a thread or hair. The manner of drawing it, see under the article GOLD *Wire*. See also WIRE, and DRAWING.

SILVER *Bluff*, in *Geography*, a headland on the coast of South Carolina, at the mouth of the river Savannah.

SILVER *Cayes*, a cluster of rocks, 10 miles S. of Grand Cayes.

SILVER *Creek*, a river of America, in Kentucky, which runs into the river Kentucky, N. lat.  $37^{\circ} 41'$ . W. long.  $84^{\circ} 40'$ .

SILVER-GRAIN, in *Vegetable Physiology*, is described by Mr. Knight, Phil. Trans. for 1801, 344, as consisting of numerous thin plates, "diverging in every direction from the *medulla* to the bark, having little adhesion to each other at any time, and less during spring and summer, than in autumn and winter; whence the greater brittleness of wood in the former seasons." The same writer remarks, that these plates are visible in every wood which he had examined, except some of the Palm tribe; but are of a different width in different kinds, lying between, and pressing upon, the sap-vessels of the *alburnum*. It may be observed, that in the oak "every tube is touched by them at short distances, and slightly diverted from its course. If these," continues Mr. Knight, "are expansible under changes of temperature, or from any cause arising from the powers of vegetable life, I conceive that they are as well placed as is possible, to propel the sap to the extremities of the branches; and their restless temper, after the tree has ceased to live, inclines me to believe, that they are not made to be idle whilst it continues alive." In support of this opinion, we would remark, that the plates in question are found where the spiral coats of the sap-vessels either no longer exist, or have lost their elasticity. See CIRCULATION of the Sap.

SILVERING, the covering of any work with a thin coating of silver. This operation is recommended by two circumstances; viz. the superior beauty of silver to that of the cheaper metals, and also its superior wholesomeness to copper, brass, or lead, for culinary purposes, as it is not corroded by vinegar and other weak acids.

Silvering may be performed on the same substances, and by similar methods with *gilding*; which see. But as works of this kind are liable to tarnish and speckle, they are seldom used. But when this is the case, the coating of silver should be much thicker than that of gold, because otherwise the friction which is necessary for removing the tarnish, would soon wear off the silver from the most prominent parts, and expose to view the subjacent copper or brass. In order to avoid this inconvenience, some have recommended, when silvering is admitted, a strong varnish, formed of some of the compositions of mastic, sandarac, the gums animi or copal, and white resin, to be put over it.

The varnish recommended in silvering leather may be applied to other purposes. See LACQUER.

The silver powder, called *argentum musivum*, may be either

tempered, in the manner of the shell-gold, with gum-water, or rubbed over a ground properly sized; and it will take a very good polish from the dog's tooth or burnishers; and hold its colour much better with a slight coat of varnish over it, than any true silver powder or leaf.

The sizes for silvering, when they are used for this purpose, ought not to be mixed, as in the case of gold, with yellow, or bole armoniac, but with some white substance, whose effect may prevent any small failures in covering the ground with the silver from being seen. This may be done with flake-white, or white-lead, when the sizes formed of oil are used; but whitening, or tobacco-pipe clay, with a little lamp-black added to it, is the proper matter in the burnish size for silvering, or wherever the glovers' or parchment size is used.

It is usual to silver metals, wood, paper, &c.

The only metals to which silvering is applied are copper and brass, and very rarely iron; and there are three modes of performing this operation, viz. by *amalgamation*, by *muriated silver*, and by *silver in substance*. The *first* mode is performed by adding plates of copper to a solution of nitrated silver, which will precipitate the silver in its metallic state, and very finely divided; scrape this from the copper, and let it be well washed and dried. With half an ounce of this powder, of common salt and sal ammoniac two ounces, and one drachm of corrosive sublimate, well rubbed together, make a paste by the addition of a little water, then clean the vessel to be silvered with a small quantity of diluted aqua fortis, or by scouring it with a mixture of common salt and tartar. Rub it, when perfectly clean, with the paste already mentioned, until it is entirely covered with a white metallic coating; which coating is an amalgam produced by the decomposition of the corrosive sublimate by means of the copper, to the surface of which it applies very closely and expeditiously. The copper thus silvered over is then to be washed, dried, and heated nearly red, for the purpose of driving off the mercury; the silver remains behind and adheres firmly to the copper, in a state capable of receiving a high polish. The *second* method of silvering is that by *luna cornea*. For this purpose, prepare the luna cornea in the usual manner, by pouring a solution of common salt into nitrate of silver, as long as any precipitation occurs, and boiling the mixture; then mix the white curdy matter thus obtained with three parts of good pearl-ash, one part of washed whitening, and a little more than one part of common salt. After the surface of the brass, cleared from scratches, has been rubbed with a piece of old hat and rotten stone, in order to remove any grease, and then moistened with salt and water, a little of the composition, being now rubbed on with the finger, will presently cover the surface of the metal with silver. Then wash it well, rub it dry with soft rag, and then, as the coat of silver is very thin, cover it with transparent varnish to preserve it from tarnish. As this kind of silvering is very imperfect, it is only used for the faces of clocks, the scales of barometers, or similar objects. (See LUNA CORNEA.) The *third* mode of performing this operation is by means of silver in substance: and of doing this there are three different methods. The *first* is by mixing together 20 grains of silver precipitated by copper, two drachms of tartar, two drachms of common salt, and half a drachm of alum; and rubbing this composition on a perfectly clean surface of copper or brass will cover it with a thin coating of silver, which may be polished with a piece of soft leather. Another and better method, called French plating, consists in burnishing down upon the surface of the copper successive layers of leaf-silver to any required thickness. Although the silver in this operation is more sold than

than in any of the former modes, the process is tedious, nor can the junctures of the leaves of silver be always entirely concealed. But the best method of all is the English plating, for an account of which see *PLATED MANUFACTURE*. Aikin's Dict.

Brass may be silvered, by boiling it with filings of good pewter and white tartar, in equal quantities. There are several other methods of silvering, for which see Smith's Laboratory, p. 37, seq.; also *Handmaid to the Arts*, vol. i. p. 471, &c. See *GILDING of Metals*.

The following is the recipe in practice with button-makers for covering the inferior kinds of plated buttons: 3lbs. of sulphate of zinc; 3lbs. of common salt; 1 oz. of corrosive sublimate; and 2 oz. of muriate of silver. This is made into a pulpy state with water, and the buttons smeared over with it. They are then exposed to a certain degree of heat, which first causes the surface to be covered with an amalgam of silver and mercury, and then expelling the latter, which requires nearly a red heat, the copper retains a permanent coating of silver. This is afterwards to be cleaned and burnished, by which it acquires a silvery lustre, which, for a time, appears like durable plating. The salt and the sulphate of zinc appear to be of no other use than to dilute and give a pulpy consistence to the mass.

Silvering in the cold is performed by the following composition: 3lbs. of cream of tartar; 3lbs. of common salt; and 1 oz. of muriate of silver, which is the precipitate formed by adding common salt to nitrate of silver, till no more is precipitated. This composition is made into a simular pulp. The surface of the copper or brass to be silvered must first be cleaned with diluted acid, and then made dry, and kept free from grease. The surface, being now rubbed with the above paste, will assume a white colour, by the silver adhering to it. This process is generally employed for silvering clock-faces, and the scales of instruments. The surface should always be varnished to prevent its tarnishing, as the silver is too thin to bear cleaning. See *BUTTON*.

*SILVERING of Leather*. See *LACQUER* and *Japanners' GILDING*.

The proceeding in silvering the leather is in all respects the same as when it is to have the appearance of gilding, except that, instead of the yellow varnish, a clear colourless one is to be used, where the appearance of silver is to be preserved.

The most common varnish for this purpose is only parchment size, made warm, and laid on with a sponge. However, the more hard and transparent the varnishes are, and the more they are of a resinous nature, the more brilliant and white, and the more durable, will be the silvery and polished appearance of the silvered leather. Some, instead of the parchment size, use that made of isinglass.

*SILVERING of Mirrors*, is the application of a coating of quicksilver to their posterior surface, in the manner briefly described under the article *LOOKING-Glasses*. The management of the silvering is, in this case, extremely simple, and is thus detailed in Aikin's Dictionary. A perfectly flat slab of free-stone (or sometimes of thick wood), a little larger than the largest plate, is inclosed in a square wooden frame or box, open at the top, and with a ledge rising a few inches on three sides, and cut down even with the stone on the fourth. A small channel or gutter is cut at the bottom of the wooden frame, serving to convey the waste mercury down into a vessel below, set to catch it. The slab is also fixed on a centre pivot, so that one end may be raised by wedges (and of course the other depressed) at pleasure, when working freely in the box.

The slab being first laid quite horizontal, and covered with grey paper stretched tight over it, a sheet of tin-foil, a little bigger than the plate to be silvered, is spread over it, and every crease smoothed down carefully; a little mercury is then laid upon it, and spread over with a tight roll of cloth, immediately after which as much mercury is poured over it as will lie on the flat surface without spilling. That part of the slab which is opposite the cut-down side of the wooden frame is then covered with parchment, and the glass plate is lifted up with care and slid in (holding it quite horizontally) over the parchment, and lodged on the surface of the slab. The particular care required here is, that the under surface of the glass should from the first just dip into the surface of the mercury (skimming it off as it were), but without touching the tin-leaf in its passage, which it might tear. By this means no bubbles of air can get between the glass and the metal, and also any little dust or oxyd floating on the mercury is swept off before the plate without interfering. The plate being then let go, sinks on the tin-foil, squeezing out the superfluous mercury, which passes into the channel of the wooden frame above-mentioned. The plate is then covered with a thick flannel, and is loaded over the whole surface with lead or iron weights, and at the same time is tilted up a little, by which still more of the mercury is squeezed out. It remains in this situation for a day, the slope of the stone slab being gradually increased to favour the dripping of the mercury. The plate is then very cautiously removed, touching it only by the edges and upper side, and the under side is found uniformly covered with a soft pasty amalgam, consisting of the tin-leaf thoroughly soaked with the quicksilver, and about the thickness of parchment. It is then set up in a wooden frame, and allowed to remain there for several days, the slope of its position being gradually increased, till the amalgam is sufficiently hardened to adhere so firmly as not to be removed by slight scratches, after which the plate is finished and fit for framing.

It is a considerable time before the amalgam has acquired its utmost degree of hardness, so that globules of mercury will often drip from new mirrors some time after they have been set up in rooms; and violent concussions of the air, such as from the firing of cannon, will often detach portions of the amalgam. These can never be perfectly replaced by any patching, as the lines of junction with the old amalgam will always be marked by white seams, seen when looking into the glass. See *FOLIATING of Looking-Glasses*.

*SILVERING of Paper*. See *Chinese PAPER*.

*SILVERIUS*, pope, in *Biography*, the son of pope Hormisdas, was placed in the pontifical chair in the year 536, upon the death of Agapetus. Belisarius, the famous general of Justinian, having soon after taken possession of Rome, the empress Theodora resolved to take this opportunity of restoring Anthemius, patriarch of Constantinople, and his party, who had been condemned for heresy by the council of Chalcedon. She wrote to Silverius, urging him to recognize Anthemius as lawful bishop, to which he gave a positive refusal. Upon this the empress made an engagement with the deacon Vigilius, that he should be raised to the popedom on condition that he would anathematize the council of Chalcedon, and re-admit Anthemius and his party; and she at the same time sent orders to Belisarius to depose Silverius. To furnish a pretext for this act, an accusation of treason was brought against the pope, as having invited the Goths to repossess themselves of Rome. This change was most probably invented for the purpose, and without the smallest foundation; and Belisarius, without acting upon it, sent for Silverius, and endeavoured by

persuasion to get him to comply with the emperor's requisition, but he remained firm. Finding, however, that he had not strength to oppose his enemies, he took sanctuary in a church; but being artfully drawn from it, he was stripped of the ensigns of dignity, and exiled in the year after he had been elected pope. When arrived at Patara, a city in Lycia, the place of his exile, the bishop of the place met him, and, indignant at the treatment he had experienced, undertook to lay the case before the emperor, then at Constantinople, and from his representation, Justinian ordered the cause to be re-heard. Silverius, immediately on receiving this order, went to Rome, where his manly conduct and personal appearance greatly disconcerted Vigilus, who had intruded into his chair. Through the intrigues, however, of Vigilus with Antonina, the wife of Belisarius, Silverius was put into his hands, and carried to the island of Palmaria, on the coast of Liguria, where he died, from want or hardship, in or about June, in the year 538; though Baronius maintains that he held a synod of four bishops in the island, at which he excommunicated Vigilus, and that he did not die till June 540. In the church of Rome he is honoured as a martyr to orthodoxy.

**SILVERMINES**, in *Geography*, a small town of the county of Tipperary, Ireland, which obtained its name from productive lead-mine in the neighbourhood, from which much virgin silver was formerly obtained. These mines, the property of lord Dunally, are no longer wrought, and are thought to be exhausted. Silvermines is north of the Keeper mountains, and gives name to a lower ridge of hills. It is 77 miles S.W. from Dublin, and about 5 miles S. from Nenagh.

**SILVES**, a town of Portugal, in the province of Algarve, situated on a river of the same name, containing 1600 inhabitants; formerly more considerable than at present, and from the year 1188 to 1580 a bishop's see, which was afterwards removed to Faro; 15 miles E.N.E. of Lagos. N. lat.  $37^{\circ} 10'$ . W. long.  $8^{\circ} 21'$ .—Also, a river of Portugal, which runs into the Atlantic, a little below Villa Nova de Portimao.

**SILVESTER I.**, pope, in *Biography*, was elected to the see of Rome in January 314. In that year was held the council of Arles, to which Silvester was invited, but he excused himself on account of his age, and sent two presbyters and two deacons as his deputies. To the general council of Nice, in 325, he also sent deputies, which council was convened by the emperor, and not by the pope, nor did the latter preside at it. It was during this pontificate that the hierarchy of the Christian church, as it has ever since existed, formed upon the model of the civil government of the empire, took its origin. Silvester died in 335, after having held the papal see nearly twenty-one years.

**SILVESTER II.**, pope, previously named *Gerbert*, was born of an obscure family in Auvergne, in the 10th century. At an early age he entered himself as a monk in the monastery of St. Gerard, Aurillac. After laying a foundation of all the sciences cultivated in that ignorant age, he travelled for improvement, and visited Spain, in order to hear the Arabian doctors in its universities. At length he rendered himself so distinguished, that he was appointed by Hugh Capet preceptor to his son Robert. At Rome he became known to the emperor Otho I., who placed him at the head of the abbey of Bobbio, about the year 970. Having resided there some years, he returned to France, but visited occasionally Italy. In one of those visits he met with Otho II. at Pavia, who took him to Ravenna, where he held a solemn deputation on a mathematical question with a Saxon, very eminent for his learning. He was

afterwards made preceptor to Otho III., who succeeded to the imperial crown while he was still a minor. In the year 991, Hugh Capet promoted him to the archbishopric of Rheims; but this elevation was a source of disquiet to him, and after much contention, he was obliged to resign the see to Arnulf, the natural son of Lothaire, king of France, who had been formerly deposed from it. This was in the year 997, and at the same time Otho III. conferred upon him the archbishopric of Ravenna; and on the death of pope Gregory V. in 999, he was elected to the papal dignity, when he assumed the name of Silvester. The acts of his pontificate were but few, and not at all important. In the year 1000 he is said to have conferred on Stephen I., king of Hungary, the royal title, with the famous crown, the palladium of that kingdom, and to have constituted him perpetual legate of the holy see, with power to dispose of all ecclesiastical benefices. An extraordinary instance of ecclesiastical vigour in this popedom is mentioned by Ademar, which, if it may be relied on, proves both the great power of the church at that period, and the disposition to abuse it. Guy, count of Limoges, having imprisoned Grimoald, bishop of that city, for taking possession of a disputed monastery, and afterwards released him, the bishop repaired to Rome, and complained to the pope, who cited Guy to his presence. The cause being heard, the count was condemned by the pope and senate to be bound to the tail of a wild horse, and dragged away till he was torn to pieces, the execution of which sentence he escaped by compromising the affair with the bishop, his accuser, and taking flight along with him. Silvester died in the year 1003. He was a very meritorious character, a promoter of learning, and a proficient in various branches of the sciences. He spent much time and large sums of money in the collection of books from various parts of Europe, composed himself a number of works, particularly in arithmetic and geometry, and with his own hands made globes, a clock, and an astrolabe. Living, as he did, in the very depths of the dark ages, he fell under the suspicion of magical practices, and several ridiculous stories are related to this purpose. There were, however, persons who knew how to appreciate his character: he is mentioned by Otho "as a most learned man, and eminent in the three branches of philosophy." He wrote a great number of letters on various topics, of which 160 of them were printed at Paris in 1611. One of these, written in the first year of his pontificate, is a call to the church universal, for delivering the Christians in Palestine; in other words, a project for a crusade.

**SILVESTRE GRANUM**, or **COCCUS SILVESTRIS**, a term used by some authors to express the *coccus Polonicus*; and by others, for a coarse or bad kind of cochineal, produced in the province of Guatimala, in New Spain; it is by some supposed to be the seed of a plant, but is, in reality, an insect, as the true cochineal is, only that the scarlet colour it yields is greatly inferior to the other. See **COCHINEAL**.

**SILVIUM**, in *Ancient Geography*, a place of Italy, in Peuceetia, E. of Venusia. The name is formed from *Silva*, a grove found in this place, and probably the "Saltus Bantini" mentioned by Horace.

**SILUM**, in *Geography*, a small island in the Adriatic. N. lat.  $44^{\circ} 39'$ . E. long.  $14^{\circ} 50'$ .

**SILURES**, or, according to the orthography of Ptolemy, *Sylures*, in *Ancient Geography*, a people of the isle of Albion, who possessed, besides the two English counties of Hereford and Monmouth, Radnorshire, Brecknockshire, and Glamorganshire, in South Wales. The northern part of

of Herefordshire has been supposed by some to belong to the Ordovices. The name of this ancient British nation is derived, by some of our antiquaries, from *coil*, a wood, and *ures*, men, because they inhabited a woody country; and by others, from the British words *es heuil iür*, which signify brave or fierce men. Tacitus has conjectured, with little probability, and no sufficient evidence, that the Silures had come originally from Spain, grounding the conjecture on a supposed, or perhaps fancied resemblance between them and the ancient Spaniards, in their persons and complexions. It is much more probable, that they, as well as the other ancient inhabitants of Britain, had come from some part or other of the neighbouring continent of Gaul. But from whencesoever they derived their origin, they reflected no dishonour upon it, as their posterity have not degenerated from them. The Silures were unquestionably one of the bravest of the ancient British nations, and defended their country and their liberty against the Romans with the most heroic fortitude. For though they had received a dreadful defeat from Ostorius Scapula, and had lost their renowned commander Caractacus, they still continued undaunted and implacable; and by their bold and frequent attacks, they at length broke the heart of the brave Ostorius. But all their efforts were at last in vain. They were repulsed by Aulus Didius, further weakened by Petilius Cerealis, and at last totally subdued by Julius Frontinus, in the reign of Vespasian. As the Romans had found great difficulty in subduing the Silures, so they took great pains to keep them in subjection, by building strong forts, and planting strong garrisons in their country. One of the most considerable of these fortifications, and the capital of the whole country, was Isea Silurum, now Caerleon, on the river Wisk, in Monmouthshire. Here the second legion of the Romans, which had contributed greatly to the reduction of the Silures, was placed in garrison (as some antiquaries have imagined) by Julius Frontinus, to keep that people in obedience. It is however certain, that this legion was very early, and very long stationed at this place. Isea Silurum was, in the Roman times, a city not only of great strength, but also of great beauty and magnificence. This is evident from the description which is given us of its ruins by Giraldus Cambrensis, in his topography of Wales, several ages after it had been destroyed and abandoned. "This (Caer Leon, or the city of the legion) was a very ancient city, enjoying honourable privileges, and was elegantly built by the Romans, with brick walls. Many vestiges of its ancient splendour are yet remaining; stately palaces, which formerly, with their gilded tiles, displayed the Roman grandeur. For it was first built by the Roman nobility, and adorned with sumptuous edifices; also an exceeding high tower, remarkable hot-baths, ruins of ancient temples, theatres encompassed with stately walls, partly yet standing. Subterraneous edifices are frequently met with, not only within the walls (which are about three miles in circumference) but also in the suburbs; as aqueducts, vaults, hypocausts, stoves, &c." This description of Caer-Leion was composed in the twelfth century, and therefore we have no reason to be surpris'd that its very ruins are now so entirely destroyed, that they are hardly discernible. On the banks of the river Wisk, besides Isea Silurum, there stood two other Roman towns; Burrium, now Usk, and Gobannium, now Abergavenny. Venta Silurum, now Caer-Gwent, near Chepstow, in Monmouthshire, was also a considerable Roman town, of which there are some faint vestiges still remaining. Blestum, in the thirteenth journey of Antoninus, is supposed to have been situated at Monmouth; and Magna, in the twelfth journey, at Kenchester, or as others think, at Ledbury, in Herefordshire. When the Roman

territories in Britain were divided into five provinces, the greatest part of the country of the Silures was in that province which was called Britannia Secunda. Henry's Hist. vol. i.

SILURUS, in *Ichthyology*, a genus of fishes of the order Abdominales, of which the generic character is as follows: The head is naked, large, broad, and compressed; the mouth is furnished with cirri, resembling the feelers of insects; the gape is very large, extending almost the whole length of the head; the lips are thick, jaws furnished with teeth; the tongue thick, smooth, and very short; the eyes are small; the gill-membrane is characterized with from four to seventeen rays; body elongated, compressed, without scales, mucous; lateral line near the back; the first ray of the dorsal or pectoral fins serrate, with reversed spines. There are twenty-eight species, divided into sections, according to the number of their cirri, as follow: the fishes in section A have *two* cirri; in section B, *four*; in section C, *six*; in section D, *eight*; and in section E, the fishes are without cirri.

The name is of Grecian origin, and is derived from the words *σειν*, to move or shake, and *ουρα*, a tail. It is given to this fish, from its remarkable quality of being almost continually moving its tail in the water.

#### Section A. Two Cirri.

##### Species.

MILITARIS. The specific character of this is, that its second dorsal fin is fleshy; cirri bony, toothed. It inhabits many rivers in Asia; feeds on smaller fishes, and grows to a large size. It is from twelve to eighteen inches long; the head and fore-parts are broad and depressed; the mouth is very wide; the teeth are small and numerous; the eyes are large; on each side the head, near the nostrils, a very strong suberest, spine, or bony process; first ray of the dorsal fin excessively large, strong, and sharply serrated, both on the middle part and towards the tip; the tail slightly bilobate, with rounded lobes. It is a native of the Indian rivers.

INERMIS. Second dorsal fin fleshy; fins unarmed. It inhabits the rivers of Surinam. This is denominated by some naturalists the subolivaceous silurus. It is transversely banded with brown spots, with unarmed fins, and flexuous lateral lines. It is about twelve inches in length; the head is bony, but smooth, and it is destitute of spiny processes. It is a native of the Indian and South American rivers.

#### Section B. Four Cirri.

##### Species.

ASOTUS. The back of this fish has only one fin: it inhabits Asia: there are two cirri above the mouth, and two beneath; the teeth are numerous; the dorsal fin is without spinous rays; the first ray of the pectoral is serrate; the anal fin is long, and connected with the caudal.

CHILENSIS. Second dorsal fin fleshy; the tail is lanceolate: it inhabits the fresh waters of Chili: it is about ten inches long; the body is brown; beneath it is white. The flesh is said to be excellent.

BAGRE. Second dorsal fin fleshy; first ray of the dorsal and pectoral fins setaceous. It inhabits South America.

CALLICHTHYS. Second dorsal fin one-rayed; a double row of scales on the sides. It inhabits the small running streams of Europe, and when these are dried up, it crawls across meadows in search of water: it is said to perforate the sides of reservoirs, for the purpose of making its escape.

Section C. *Six Cirri.*

## Species.

**GLANIS**, or European Silurus. This is also called the great or common silurus, and may be considered as the largest of all European river-fish, growing, in some cases, to the length of eight, ten, twelve, or even fifteen feet, and to the weight of 300 pounds. Its more general length, however, is from two to four feet. The head is broad and depressed; the body thick, and of a lengthened form, with the abdomen very thick and short. It is of a sluggish disposition, being rarely observed in motion, and commonly lying half imbedded in the soft bottom of the rivers which it frequents, under the projecting roots of trees, rocks, logs, or other substances. In this situation it remains, with its wide mouth half open, gently moving about the long cirri situated on each side the jaws, which the smaller fishes mistaking for worms, and attempting to seize, become a ready prey to the silurus. The colour of this species is dark olive, varied with irregular spots of black; the abdomen and lips are of a pale flesh-colour, and the fins are tinged with violet. It is an inhabitant of the larger rivers of Europe, as well as some parts of Asia and Africa, but it appears to be most plentiful in the north of Europe. It is not much esteemed as food, the flesh being of a glutinous nature; but from its cheapness, it is in much request among the inferior ranks of society, and is eaten either fresh or salted. The skin, which is smooth, and destitute of apparent scales, is dried and stretched, and after rubbing with oil, becomes of a horny transparency and strength, and is used in some of the northern regions instead of glass for windows. The silurus is not a very prolific fish, depositing a small quantity of spawn, consisting of large globules or ova; these, as well as the newly hatched young, are frequently the prey of other fishes, frogs, &c., and thus the great increase of the species is prevented. The ova are said to be hatched in about a week after their exclusion.

**ELECTRICUS**. The dorsal fin is single and fleshy. The head is depressed; the eyes are moderate, covered with the common skin; the teeth are crowded, small, and sharp in each jaw; the nostrils are very minute; each side approximate; upper lip bearded with two cirri, the lower with four, of which the exterior ones are longer. It inhabits the rivers of Africa. It is about twenty inches long; the body is long and broad on the fore part, depressed, pale ash-colour, with a few blackish spots towards the tail; when touched, it communicates a trifling shock, attended with a sort of trembling and pain in the limbs, but less violent than that given by the

**TORPEDO**, which see. The flesh of the electrical silurus is eatable.

**FELIS**. The second dorsal fin of the fish of this species is fleshy; it has 23 anal rays; the tail is bifid. It is found in Carolina; the body above is blueish.

**GALEATUS**. The second dorsal fin of this fish is fleshy; it has 24 anal rays, and the tail is entire. It inhabits South America. The head is covered with a hard coriaceous shield; the spinous rays of the pectoral and dorsal fins are rigid.

**CARINATUS**. Second dorsal fin fleshy; the lateral line is spinous; the cirri under the lower lip are connected. It inhabits Surinam; the body is compressed.

**NILOTICUS**. The second dorsal fin of this is fleshy; the anal rays are ten in number. It is found in the Nile; is fourteen inches and a half long; the body is of a brownish-grey; the sides of the head are blueish; the end of the nose, under part of the head, pectoral fins and cirri, are

tinged with red: there is a fennecircle of reddish at the commencement of the tail.

**GLARIAS**. Second dorsal fin fleshy; anal rays eleven. It inhabits the rivers of South America and Africa; is from twelve to fifteen inches long; the body is of a blackish-ash, beneath it is hoary; it is said to inflict venomous wounds with the ferrated pectoral fin.

**FASCIATUS**. Second dorsal fin fleshy; the anal rays are thirteen. It inhabits Surinam and the Brazils: the body is black, with white bands on each side, beneath it is white; the flesh is in high esteem; the head is depressed, rounded on the fore part; a third part as long as the whole body; the fins are all spotted with black.

**ASCITA**. The second dorsal fin fleshy; it has eighteen anal rays. It inhabits India, and appears to be of a mixed kind between oviparous and viviparous.

**COSTATUS**. Second dorsal fin is fleshy; a single row of scales on the sides; the tail is bifid. It inhabits South America and India.

**CATAPHRACTUS**. Second dorsal fin of one ray; a single row of scales on the sides; the tail is entire. It inhabits South America.

Section D. *Eight Cirri*

## Species.

**ASPREDO**. Dorsal fin single, five-rayed. It is found in the rivers of America. The base of the lateral cirri broad; the back carinate; the anal fin reaching to the tail; the tail is forked.

**MYSTUS**. The dorsal fin is single, and single-rayed. It inhabits the Nile: the tail is forked.

**ANGUILLARIS**. Dorsal fin single, seventy-rayed. It is found in the Nile: the upper part of the head is greenish; the body above the lateral line is marbled with blackish and grey; the belly and lower jaw are of a reddish-grey; the pectoral fins are transversely divided by a broad red band.

**BATRACHIUS**. Dorsal fin is single, and sixty-rayed. It inhabits Asia and Africa: the tail entire.

**UNDECIMALIS**. The dorsal fin is single, and eleven-rayed. It inhabits Surinam: the tail is forked.

**CATES**. Second dorsal fin fleshy, anal twenty-rayed. It inhabits Asia and America.

**COUS**. Second dorsal fin fleshy, anal eight-rayed; tail forked. It inhabits Syria: the cirri are shorter than the head.

**DOCMAC**. Second dorsal fin fleshy, anal ten-rayed. The length of the fish of this species is about three feet. It is of a grey colour, whitish beneath: the head is depressed; body convex above; mouth furnished with eight beards, the exterior ones of the upper lip extending half the length of the body; the lateral line is straight, and situated nearer the back than the abdomen; the first ray of the dorsal and anal fins long and ferrated, with soft tip. It is a native of the Lower Nile, towards the Delta.

**BAJAD**. Second dorsal fin fleshy, anal twelve-rayed. It is about a foot in length; the colour is glaucous; the head obtuse, depressed, and marked on each side, before the eyes, by an unequal pit or depression; the upper jaw is longer than the lower; exterior beards of the upper lip very long; lateral line at first descending, then straight; above the pectoral fins on each side is a very strong spine, ferrated in a reversed direction; the fins are rufous; the second dorsal or adipose fin is long; the tail is long, dilated towards the tip, and forked. It is a native of the Nile.

## Species.

**CORNUTUS.** First ray of the first dorsal fin serrate; pectoral unarmed. It is not more than eight or nine inches long; the shape is oval; body carinated beneath; the snout is straight, compressed, a little recurved at the tip, and about half the length of the body; the first ray of the first dorsal fin extending as far as the middle of the tail, and serrated beneath for about half its length. It is a native of the Mediterranean.

**IMBERBIS.** The gill-covers with two spines on the hind part. It inhabits Japan, and is about six inches long; the body is funnel-shaped, reddish, and coated with scales. It is a native of the Indian and South American rivers.

**SILURUS** is also a name given by some authors to the sturgeon, called by others *accipenser*, but by the generality of writers *flurio*.

**SILURUS Mons,** in *Ancient Geography*, a mountain of Hispania, in the vicinity of Bætica.

**SILUUM,** a town of Asia Minor, in the interior of Pamphylia. Ptolemy.

**SILYBUM,** in *Botany*, a name borrowed from Dioscorides, whose *σιλύβιον* is described as a large kind of thistle, eatable when young, if dressed with oil and salt. A liquor, which exuded from its root, was given, in the dose of a drachm, mixed with water, to excite vomiting. Gærtner, after Vaillant, has applied the name in question to a genus of his own, under which he brings together *Carduus marianus* and *Cnicus cernuus* of Linnæus, two very dissimilar plants.

**SIM,** in *Geography*, a river of Russia, which runs into the Yenisei; 6 miles N. of Balagovetschenkoi. N. lat. 60° 10'. E. long. 90° 40'.

**SIMA,** or **CYMA,** in *Architecture*, a term used by Wolfius, and some other writers, for what we otherwise call *cyathium*, or *smatium*.

**SIMABA,** in *Botany*, the name of a shrub in Guiana, described by Aublet, 400. t. 153; for which, being barbarous, Schreber has substituted the more legitimate, if not more harmonious, one of **ZWINGERA**; see that article hereafter.

**SIMÆTHUS,** or **SIMETUS,** now *Giaretta*, or *St. Paul*, in *Ancient Geography*, a river in the eastern part of Sicily, which passed through the territory of the city of Leontini, and which was celebrated by the poets. The nymph Thalia, after her amour with Jupiter, is supposed to have been converted into this stream, which, to avoid the rage of Juno, sunk under ground near mount Ætna, and continued this subterraneous course to the sea. In the time of the Romans it was navigable. It takes its rise on the N. side of Ætna, and surrounding the west skirts of the mountain, falls into the sea near the ruins of the ancient Morgantio. It does not now sink under ground; but throws up near its mouth great quantities of amber, which the peasants gather, and carry to Catania, where it is manufactured in the form of crosses, beads, faints, &c. and is sold at very high prices to the superstitious people on the continent. There is a large sandy beach, that extends from the mouth of this river a great way to the S. of Catania, and was, without doubt, continued the whole way to the foot of the mountain Taurominum; but it was broke in upon, at a remote period, by the lavas of Ætna, which, from a low sandy shore, have now converted it into a high, bold, black iron coast. Aiter piercing through the lava, beds of shells and sea-sand have been discovered.

**SIMALISCHEVA,** in *Geography*, a town of Russia,

in the government of Kolivan; 40 miles S.S.E. of Kolivan.

**SIMANA,** in *Ancient Geography*, a town of Asia, in Bithynia, situated between two rivers.

**SIMANCAS,** in *Geography*, a small town of Spain, in the province of Leon, near the confluence of the rivers Pisuerga and Duero, celebrated for a white wine, that is very much esteemed. In the time of Philip II. it was a strong place, in which he ordered the archives of the kingdom to be kept. It was taken by the Moors in the year 967; 8 miles S.W. of Valladolid.

**SIMAR,** a town of Hindoostan, in the circar of Gohud; 14 miles E. of Gohud.

**SIMARA,** one of the smaller Philippine isles; 24 miles E. of Mindanao. N. lat. 12° 5'. E. long. 121° 40'.

**SIMARIA,** a town of Naples, in Calabria Ultra; 4 miles E.N.E. of St. Severina.

**SIMARONA,** a name given by the Spaniards in America to a species of vanilla, called also *bastard-vanilla*. The pods of this kind are every way smaller than those of the true kind, and have very little liquor or pulp in them when broken, and contain very few seeds. These are greatly inferior to the true kind, having scarcely any smell. It is not yet certainly known whether this species be the fruit of a different kind of vanilla-plant from the common, or whether it be the fruit gathered at a different season, or from a plant growing in a different soil. See **VANILLA**.

**SIMARONES,** in *Geography*, a town of the island of Cuba; 105 miles E. of Havanna.

**SIMAROUBA,** or **SIMARUBA,** in *Botany*, is the bark of the roots of a tree, first imported into Europe in the year 1713, but not long ago botanically ascertained to be a species of the *Quassia*; which see.

**SIMAROUBA,** or **SIMARUBA,** in the *Materia Medica*. This bark, according to Dr. Wright's account of it, is rough, fealy, and warted. The inside, when fresh, is a full yellow, but when dry, paler; it has but little smell: the taste is bitter, but not disagreeable. Macerated in water, or in rectified spirit, it quickly impregnates both menstrua with its bitterness, and with a yellow tincture. It seems to give out its virtue more perfectly to cold, than to boiling water; the cold infusion being rather stronger in taste than the decoction; which last, of a transparent yellow colour whilst hot, grows turbid and of a reddish-brown as it cools. The milky appearance, which Jussieu says it communicates to boiling water, Dr. Wright has not observed in the decoction of any of the specimens which he has examined.

The bark was first sent from Guiana to France, in 1713, to the count de Porchartrain, then secretary of state, as a remedy of great efficacy in dysentery. In the years 1718 and 1723, an epidemic flux prevailed very generally in France, which resisted all the medicines usually employed in such cases; small doses of ipecacuanha, mild purgatives, and all astringents, were found to aggravate, rather than to relieve, the disease: under these circumstances, recourse was had to the cortex simaruba, which proved remarkably successful, and first established its medical character in Europe. Dr. Wright says, "most authors who have written on the simaruba, agree, that in fluxes it restores the lost tone of the intestines, allays their spasmodic motions, promotes the secretions by urine and perspiration, removes that lowness of spirits attending dysenteries, and disposes the patient to sleep; the gripes and tenesmus are taken off, and the stools are changed to their natural colour and consistence. In a moderate dose it occasions no disturbance or uneasiness, but in large doses it produces sickness at the stomach and vomiting.

“Modern physicians have found from experience, that this medicine is only successful in the third stage of dysentery, where there is no fever, where too the stomach is no way hurt, and where the gripes and tenesmus are only continued by a weakness of the bowels. In such cases, Dr. Munro gave two or three ounces of the decoction every five or six hours, with four or five drops of laudanum; and found it a very useful remedy. The late sir J. Pringle, Dr. Huck Saunders, and many others, prescribed the cortex fimaruba in old and obstinate dysenteries and diarrhoeas, especially those brought from warm climates. Fluxes of this sort, which were brought home from the siege of Martinico and the Havannah, were completely and speedily cured by this bark. The urine, which in those cases had been high-coloured and scanty, was now voided in great abundance, and perspiration restored. Dr. James Lind, at Haslar Hospital, says, that the fimaruba produced these effects sooner, and more certainly, when given in such quantity as to nauseate the stomach. Dr. Huck Saunders remarks, that if the fimaruba did not give relief in three days, he expected little benefit from its farther use; but others have found it efficacious in fluxes, after a continued use for several weeks. My own experience, and that of many living friends, are convincing proofs to me of the efficacy of this medicine, and I hope the fimaruba bark will soon be in more general use.”

Dr. Wright recommends two drachms of the bark to be boiled in twenty-four ounces of water to twelve; the decoction is then to be strained and divided into three equal parts, the whole of which is to be taken in twenty-four hours, and when the stomach is reconciled to this medicine, the quantity of the bark may be increased to three drachms. To this decoction some join aromatics, others a few drops of laudanum to each dose.

Dr. Cullen says, that the virtues ascribed to fimaruba have not been ascertained by his own experience, or that of the practitioners in Scotland. Woodv. Med. Bot.

SIMAROW, in *Geography*, a town of Hindoostan, in Bahar; 13 miles S.S.W. of Arrah.

SIMARUM MUSCULUS, in *Anatomy*, a name given by some of the old writers to a muscle, called by the moderns the *ferratus magnus*.

SIMAS, in *Ancient Geography*, a promontory in the Euxine sea, on which Venus had a statue.

SIMATIUM, or SIMAISE, in *Architecture*. See CYMATIUM.

*Simatium* and *cymatium* are generally confounded together, yet they ought to be distinguished; the latter being the genus, and the former the species.

*Simatium*, of *simā*, camous, according to Felibien, is the last and uppermost member of grand corniches, called particularly the great *doucine*, or *gula recta*; and by the Greeks, *epititheta*.

In the antique buildings, the *simatium*, at the top of the Doric corniche, is generally in form of a cavetto, or semiscotia; as we see particularly in the theatre of Marcellus. This some modern architects have imitated; but, in the Ionic order, the *simatium* is always a *doucine*.

The *simatium*, or *doucine*, then, is distinguished from the other kinds of *cymatia*, by its being camous or flat-nosed.

SIMBALATHI, in the *Materia Medica*, a name given by Avicenna and others to the spikenard, or *nardus Indica*.

The exact interpretation of the word is *spicigera*, and Avicenna, under this general name, distinguishes it into several kinds; the first he calls *alnardin*, or *nardin*. It has been supposed by some that he means the Indian spikenard

by this word; but, on the contrary, it appears plainly that he means the Celtic nard: he calls it the *nardus Romani orbis*, and says that it is of European growth. After this he mentions the Asiatic nards of several kinds, which are only the Indian spikenard, growing in different places, and such as used to be brought thence in different degrees of perfection.

SIMBANI, in *Geography*, a tract of country in Asia, abounding with woods, and uncultivated, lying between the kingdom of Woolli to the north-west, Foota Torra to the north, Bondou to the north-east, and Tenda to the south-west.

SIMBING, a town of Africa, in Ludamar; 5 miles S.W. of Jarra.

SIMBIRSK, a town of Russia, and capital of a government, on the Volga; 380 miles E.S.E. of Moscow. N. lat. 54° 25'. E. long. 48° 30'.

SIMBIRSKOE, a government of Russia, bounded on the north by Kazanskoe, on the west by Nizegorodskoe and Penzenskoe, on the south by the government of Saratov, and on the east by Uphinskoe; about 180 miles from east to west, and 140 from north to south. N. lat. 52° 20' to 55° 30'. E. long. 45° to 51°.

SIMBOLAN, a town of South America, in the province of Tucuman; 85 miles S.E. of Rioja.

SIMBULETA, in *Botany*, altered by Forskall from the Arabic *Symbulet ennefem*.—Forsk. *Ægypt-Arab.* 115. Juss. 418.—Class *Didymia*; Order probably *Angiosperma*. Nat. Ord. uncertain.

Ess. Ch. “Calyx five-cleft. Corolla bell-shaped, ringent. Anthers combined.”

Descr. “*Stem* annual, a foot high, simple, slender, erect, round, with some appearance of angles. *Leaves* feathered, near to each other, linear-thread-shaped; the upper ones simple, half an inch long; lower an inch long, in two deep, pointed, smooth divisions. *Cluster* terminal, four inches in length. *Flowers* solitary, drooping, on short stalks, with a short, linear, leafy *bractea* under each. *Calyx* a perianth of one leaf, bell-shaped, permanent, in five linear equal segments. *Corolla* of one petal, ringent, white; tube bell-shaped, longer than the calyx; upper lip of the limb reflexed, cloven; lower longest, three-lobed, straight, its middle lobe inflexed. *Filaments* four, inserted into the corolla, two of them longest. *Anthers* four, black, united into a quadrangular compressed plate. *Germen* ovate. *Style* thread-shaped. *Stigma* capitate, ovate, nearly globose, oblique. *Fruit* not observed. The aspect of the plant is exactly that of a *Reseda* or *Polygala*; it moreover approaches the character of *Columnnea*, as to the combined anthers, but differs in many other respects.” Found on mount *Kurma*, and no where else, by Forskall, whose description has not enabled any learned botanist to guess at the plant, except that Jusseu thinks it may be akin to *Veronica*, or to Aublet’s *Piripea*. We should rather suspect an affinity to *Antirrhinum*.

SIMCOE LAKE, in *Geography*, a lake of Upper Canada, formerly lake Aux Claires, situated between York and Gloucester, and communicating with lake Huron. It has a few small islands; and several good harbours.

SIMELIUM, a Latin term, used by some to signify a table, with ranges of little cavities in it, for the disposing of medals in chronological order.

The word is but ill written; it should rather be *simulium*, as being formed of the Greek *σινεσιον*, *curiosities*, or a cabinet of precious things.

We more usually say, a cabinet of medals, than a *simelium*.

SIMENA, in *Ancient Geography*, a town of Asia Minor, in Lycia. Steph. Byz.

SIMENAU, in *Geography*, a town of Prussia, in the province of Oberland; 8 miles E. of Salfeld.

SIMEON, in *Scripture Biography*, a son of Jacob and Leah, born in the year 1757 B.C. (Gen. xxix. 37.) Simeon and Levi revenged the affront, sustained by the defilement of their half-sister Dinah on the part of Schechem, the son of Hamor, by entering the town of Schechem, and killing all the men they found; after which they brought away Dinah, in the year 1739 B.C. (Gen. xxxiv. 25.) It has been thought that Simeon was the most cruel to his brother Joseph, and that he advised his brethren to sell him. (Gen. xxxvii. 20.) The conjecture is founded on the circumstance of his being detained prisoner in Egypt (Gen. xlii. 24.) and of his being treated with greater rigour by Joseph than the rest of his brethren. Jacob, on his death-bed, manifested peculiar indignation against Simeon and Levi. (See Gen. xlix. 5.) Accordingly the tribes of Simeon and Levi were dispersed in Israel. Levi had no compact lot or portion; and Simeon received for his portion only a district dismembered from the tribe of Judah (Josh. xix. 1, 2, &c.), and some other lands which were over-run by those of this tribe on the mountains of Seir, and in the desert of Gedor. (1 Chron. iv. 24. 39. 42.) The Targum of Jerusalem, and the rabbins, who have been followed by some of the fathers, have affirmed, that the greater part of the scribes and men learned in the law were of this tribe; and as these were dispersed throughout Israel, we perceive the accomplishment of Jacob's prophecy, which foretold that Simeon and Levi should be scattered among their brethren. It has been suggested, however, that the dispersion of Simeon and Levi, which Jacob meant to be a degradation, was in the progress of events over-ruled so as to be an occasion of honour; for Levi had the priesthood, and Simeon had the learning or writing-authority of Israel; in consequence of which both these tribes were honourably dispersed throughout Israel. According to the testament of the twelve patriarchs, a book indeed of no authority, Simeon died at the age of 120 years.

The sons of Simeon were six, and are enumerated Exod. vi. 15. Their descendants amounted to 59,300 men, at the Exodus (Numb. i. 22.); but the number of those that entered the Land of Promise amounted only to 22,200, the rest having died in the desert. (Numb. xxvi. 14.) The portion of Simeon was west and south of that of Judah; having the tribe of Dan and the Philistines north, the Mediterranean west, and Arabia Petraea south. Josh. xix. 1—9. Calmet.

SIMEON is also the name of that aged and pious person, mentioned Luke, ii. 25, 26, to whom Jesus Christ was presented by his parents in the temple, and who pronounced upon them his blessing. It is believed, with good reason, that he died soon after he had borne his testimony to Christ. Some, indeed, have pretended, that this Simeon was the same as Simeon the just, the son of Hillel, and master of Gamaliel, whose disciple St. Paul was.

SIMEON, or SIMON, was also the name of our Lord's cousin-german, son of Cleophas and of Mary, the sister of Christ's mother, probably the same with him who is named Simon by St. Mark (ch. vi. 3.) He was probably one of our Lord's first disciples. According to Eusebius, he was unanimously elected bishop of Jerusalem, after the death of St. James, A.D. 62. When the emperor Trajan made strict inquiry for all who were of the race of David, Simon was accused before Atticus, the governor of Palestine; and having endured many sufferings with a fortitude which asto-

nished observers, at the age of 120 years, he was crucified about A.D. 107; so that he had superintended the church of Jerusalem about 43 years. The Latins place his feast February 18, the Greeks April 27.

SIMEON, in *Biography*, the son of Jochai, a very celebrated man among the Jews, was a scholar of the rabbi Akiba, and flourished about the year 120. At the insurrection excited by Barchocheba, he fled, through fear of the Romans, and retired to a cave, where he concealed himself twelve years, in the course of which he is said to have composed his work, entitled "Sohar," which is an explication of the five books of Moses. This, from its abstract manner, and the matter being clothed, according to the Egyptian method, in hieroglyphical images and very florid language, is not easily understood. There are several editions of it, but its exact age is not known. It contains things that are very old; but it is admitted by Christians, as well as Jews, who held it in esteem, to be the production of more authors than one, and to have been enlarged, from time to time, by various additions. Gen. Biog.

SIMEON, surnamed *Metaphrastes*, an ecclesiastical writer, lived in the tenth century, under Leo the philosopher and his son Constantine Porphyrogenitus. He was a native of Constantinople, and rose to high employments at court, having been secretary to the emperors, and the medium of communication between them and foreigners. His writings indicate a man conversant in ecclesiastical affairs. He derived his surname of Metaphrastes, or Translator, from his occupation of writing again, in a different style, not translating, the lives of the saints. In this business he evidently meant to give a panegyric, rather than a true history; whence he has made additions and alterations at pleasure, so that the subjects are represented not as they were, but as he imagined they ought to be. His "Lives of the Saints" have several times been translated into the Latin language. Simeon likewise composed sermons, hymns, and prayers, with various pieces of the religious kind, of which some have been printed, and others remain in manuscript.

SIMEON, named *Stylites*, a distinguished person in the annals of fanaticism, was born about the year 392 at Sison, a town on the borders between Syria and Cilicia. He was the son of a shepherd, and followed the same occupation to the age of thirteen, when he entered into a monastery. After some time he left it, in order to devote himself to a life of greater solitude and austerities, and he took up his abode on the tops of mountains, or in caverns of rocks, fasting sometimes, it is said, for weeks together, till he had worked himself up to a due degree of extravagance. He then, to avoid the concurrence of devotees, but probably to excite still greater admiration, adopted the strange fancy of fixing his habitation on the tops of pillars, whence the Greek appellation; and with the notion of climbing higher and higher towards heaven, he successively migrated from a pillar of 6 cubits to one of 12, 20, 36, and 40. This feat was considered as a proof of extraordinary anxiety, and multitudes flocked from all parts to pay their veneration to the holy man, as he was denominated. Simeon passed 47 years upon his pillars, exposed to all the inclemency of the seasons. At length a horrible ulcer put an end to his life, at the age of 69. His body was taken down from his last pillar by the hands of bishops, and conveyed to Antioch, with an escort of 6000 soldiers; and he was interred with a pomp equal to any thing that had been displayed for the most potent monarchs. He has been enrolled among the saints, either in the Greek or Latin churches. These honours produced imitators, whose performances surpassed the original. One of them inhabited his pillar 68 years.

The madnes remained in vogue till the twelfth century, when it was suppressed.

SIMON BEN JOCHAL. See CABBALA.

SIMERCHEIT, in *Geography*, a town of Bohemia, in the circle of Boleslaw; 4 miles N. of Melnik.

SIMEREN, a river of Syria, which runs into the Euphrates, at Romkala.

SIMERING, a town of Austria; 4 miles S.S.E. of Vienna.

SIMI, or SYMI, an island in the Mediterranean, between the island of Rhodes and the continent of Asia; 6 miles N. of Rhodes. N. lat.  $36^{\circ} 36'$ . E. long.  $37^{\circ} 34'$ .

SIMIA, in *Natural History*, a genus of the class and order of Mammalia Primates, of which the generic character is, that the individuals have four front teeth in each jaw, which are approximate; the tusks are solitary, longer, and more remote; the grinders obtuse. The animals of this genus greatly resemble man in the uvula, eye-lashes, hands, feet, fingers, toes, nails, and other parts of the body; they, however, differ widely in the total want of reason: they have retentive memories, are imitative, and full of gesticulations; chatter with their teeth, and grin: they macerate their food in the cheeks before they swallow it: they are filthy, lascivious, thieving, gregarious, and the prey of leopards and serpents, the latter pursuing them to the summits of trees and swallowing them entire.

This race of animals, which is very numerous, is almost confined to the torrid zone; they fill the woods of Africa, from Senegal to the Cape, and from thence to Ethiopia: a single species is found beyond that line, in the province of Barbary: they are found in all parts of India, and its islands; in Cochinchina, in the south of China, and in Japan; and one kind is met with in Arabia: they swarm in the forests of South America, from the isthmus of Darien as far as Paraguay.

These animals, from the structure of their members, have many actions in common with the human kind; most of them are fierce and untameable; some are of a milder nature, and will shew a degree of attachment: they feed on fruits, leaves, and insects; inhabit woods, and live in trees: they go in large companies. The different species never mix with each other, but always keep apart: they leap with great activity from tree to tree, even when loaded with their young, which cling to them: they are not carnivorous, but, for the sake of mischief, will rob the nests of birds of the eggs and young; and it is observed, that in those countries where apes most abound, the feathered tribe discover singular sagacity in fixing their nests beyond the reach of these invaders.

Mr. Ray first distributed the animals of this genus into three classes, *viz.* the *simiæ*, or apes, such as wanted tails; the *cercopithecæ*, or monkeys, such as had tails; and *papiones*, or baboons, those with short tails.

From Ray, Linnæus formed his method, which was followed by M. de Buffon, who made a farther sub-division of the long-tailed apes, or true monkeys, into such as had prehensile tails, and such as had not.

The genus is divided into the following sections:

- Section A. APES without any tail.
- B. BABOONS with short tails.
- C. MONKEYS. Tails long, not prehensile; cheeks pouched; haunches naked.
- D. SAPIJONS. Tails prehensile; no cheek-pouches, and their haunches are covered.
- E. SAGOINS. Tails not prehensile; no cheek-pouches; haunches covered.

Of the whole genus, says Dr. Shaw, it may be observed that the baboons are commonly of a ferocious and sullen disposition. The larger apes are also of a malignant temper, except the orang-outang and the gibbons. The monkeys, properly so called, are extremely various in their dispositions; some of the smaller species are lively, harmless, and entertaining; while others are as remarkable for the mischievous malignity of their temper, and the capricious uncertainty of their manners. It is no easy task to determine with exact precision the several species of this extensive genus; since, exclusive of the varieties in point of colour, they are often so nearly allied as to make it difficult to give real and distinctive characters. We shall, as usual, follow Gmelin's *Systema Naturæ* of Linnæus, in which there are sixty-four species delineated.

#### Section A. APES without Tails.

##### Species.

TROGLODYTES, or Angola Ape. The generic character is, that the head is conic, body brawny, back and shoulders hairy, the rest of the body smooth.

SATYRUS; Orang-outang. Rusty-brown, hair of the fore-arms reversed, haunches covered. Besides this there are two varieties; 1. Without cheek-pouches, or callosities on the haunches. This variety always walks erect. Its trivial name is Pongo. It inhabits Java and Guinea, and is from five to six feet high. 2. The other variety resembles the former, but is above half as high: it is docile, gentle, and grave, and by some thought to differ from the other only in age.

Of these animals, the species which has most excited the attention of mankind is the orang-outang, or, as it is often denominated, the satyr, great ape, or wild man of the woods. It is a native of the warmer parts of Africa and India, and also of several of the Indian islands, where it resides principally in the woods, and is supposed to feed, like most other of this genus, on fruits. The orang-outang appears to admit of considerable variety in point of colour, size, and proportion; and there is reason to believe, that in reality there may be two or three kinds, which, though nearly approximated as to general similitude, are yet specifically distinct. The specimens imported into Europe have rarely exceeded the height of two or three feet, though full-grown ones are said to be six feet in height. The general colour seems to be of a dusky brown; the face is bare; the ears, hands, and feet nearly similar to the human; and the whole appearance is such as to exhibit the most striking approximation to the human figure. The likeness, however, is only general, and will not bear the test of examination; and the structure of the hands of the feet, when observed with anatomical correctness, seems to prove that the animal was principally designed by nature for walking on four legs, and not for an upright posture, which is only occasionally assumed, and which is thought to be the effects of instruction rather than truly natural.

The manners of the orang-outang, when in captivity, are gentle, and perfectly void of that disgusting ferocity which is often conspicuous in some of the larger baboons and monkeys. It is mild and docile, and may be taught to perform a variety of actions in domestic life. But, however docile and gentle when taken young, and instructed in its behaviour, it is possessed of great ferocity in its native state, and is considered a very dangerous animal, capable of readily overpowering the strongest man. Its swiftness is equal to its strength; and hence it can rarely be obtained in its full-grown state.

M. Vofmaer's account of the manners of the orang-outang brought into Holland in 1776, and presented to the prince of Orange, is nearly as follows. It was a female, about  $2\frac{1}{2}$  Rhenish feet. It shewed no symptoms of fierceness and malignity, and was of rather a melancholy appearance. It was fond of company, and shewed a marked preference to those who took daily care of it, of which it seemed very sensible. When the company retired, it would frequently throw itself on the ground, as if in despair, uttering lamentable cries, and tearing in pieces the linen within its reach. Its keeper having sometimes been accustomed to sit near it on the ground, it took the hay off its bed and laid it by its side, and seemed, by every demonstration, to invite him to be seated near. Its usual manner of walking was on all fours, but it could walk on its two hinder feet only. One morning it got unchained, and was seen to ascend the beams and rafters of the building with wonderful agility, and it was with the utmost difficulty retaken and secured. During its state of liberty it had taken out the cork from a bottle of Malaga wine, which it drank to the last drop. It would eat every thing that was offered, but was not observed to hunt for insects like other monkeys; it was fond of eggs, but fish and roasted meat seemed its favourite food. It had been taught to eat with a spoon and fork. Its common drink was water, but it would drink any kind of wine. At the approach of night it lay down to sleep, and prepared its bed by shaking well the hay on which it slept, and putting it in proper order, and lastly covering it with a coverlet. This animal lived seven months in Holland. On its first arrival, it had but little hair, except on its back and arms, but on the approach of winter it became well covered, and the hair on the back was full three inches long. The whole animal then appeared of a chestnut-colour; the skin of the face, &c. was of a mouse-colour, but about the eyes and round the mouth it was of a dull flesh-colour. It was imported from the island of Borneo. See ORANG-OUTANG.

In Dr. Gmelin's edition of the *Systema Naturæ*, says Dr. Shaw, the smaller variety, or the jocko, in its less shaggy or more naked state, is given as a distinct species under the name of *S. troglodytes*. The print published many years past, by the name of Chimpanzee, is of this kind. (See CHIMPANZEE.) The animal described in the 59th volume of the *Phil. Trans.* is by Gmelin referred to the orang-outang; but Mr. Pennant describes it under the title of Golok. It has a pointed face; long and slender limbs; arms, when the animal is upright, not reaching lower than the knees; head round, and full of hair; grows to the height of a man. It inhabits the forests of Mevat, in the interior parts of Bengal. In its manners it is gentle and modest, distinguished from the orang-outang by its slender form. In colour it is entirely black. In the *Philosophical Transactions* the description is as follows. "The animal is said to be the height of a man, the teeth white as pearls; the arms in due proportion, and the body very genteel."

LAR, or long-armed Ape, has its haunches naked; its arms as long as its body: it is found in India, is gentle, slothful, impatient of cold and rain, and is four feet high. There are two other varieties, of which the first is about eighteen inches high, the face and body brown. The second has its body and arms covered with silvery hair; the face, ears, crown, and hands, are black. It inhabits the forests of Deval, in Bengal, is playful, gentle, and elegant: about three feet high. The lar, or, as it is sometimes denominated, the gibbon, is distinguished by the length of its arms, which, when the animal stands upright, are capable of touching the ground with its fingers; hence its trivial name. Notwith-

standing the apparent ferocity of the lar, and the deformity of its figure, which is extremely well given by Dr. Shaw, it is of a tractable and gentle nature, and has even been celebrated for the decorum and modesty of its behaviour. Considered with respect to the rest of the genus, it ranks among the genuine apes, or those which have not the least vestige of a tail; and, says the naturalist already quoted, alarms the pride of mankind, by too near an approach to the real primates of the creation.

SYLVANUS; Pigmy. Haunches naked; head roundish; arms shorter. It inhabits Africa and the island of Ceylon; is mild and easily tamed; it uses threatening gestures when it is angry, chatters when pleased, salutes after the manner of the Hottentots, and drinks from the palm of the hand. The face is short and flat; the forehead transversely projecting at the regions of the eye-brows; the skin is rough; the hair on the neck and fore-arms reversed: it is about eighteen inches high.

INUUS; denominated by Buffon the Magot, and by Pennant the Barbary Ape. Its haunches are naked, and the head oblong. It inhabits Africa, is fond of the open air, deformed, dirty, and melancholy. It a good deal resembles the *S. sylvanus*, but its snout is longer, colour paler, nails rounded, and is about three feet and a half high. This is what is commonly seen in the exhibition of such kind of animals: it is not remarkable for docility or good temper; but, by force of discipline, it is made to exhibit a greater degree of intelligence than many others. Its colour is an olivaceous-brown, paler or whiter beneath; the face is of a swarthy flesh-colour. The hands and feet have nails resembling the human. It is destitute of any real tail, but there is commonly a short skinny appendix in the place of one.

This animal inhabits many parts of India, Arabia, and all parts of Africa, except Egypt, and a small number is found on the hill of Gibraltar, which breed there. These apes are very ill-natured, mischievous, and fierce, agreeing with the character of the ancient cynocephali: they are often exhibited to play tricks; assemble in great troops in India; and will attack women going to market, and rob them of their provisions. The females carry their young in their arms, and will leap from tree to tree with them.

SULLA; or Hog-faced Ape. Nose blunt, truncate, resembling that of a hog.

Section B. BABOONS with short Tails. See BAROON.

NEMESTRINA. Beard thin; colour grey; eyes hazel; haunches naked. It inhabits Sumatra and Japan; is lively, gentle, tractable, and impatient of cold. The face is naked and tawny; the nose is flat; lips thin, with hairs resembling whiskers; hair on the body olive-black; belly reddish-yellow: it is about two feet high. This species is figured by Mr. Edwards, who was in possession of the living animal, and who, in order to compare his specimen with a much larger animal of the same species, carried it to Bartholomew fair, and he said they seemed highly delighted with each other's company, though it was the first time of their meeting: the best figure of this species is said to be that given by Buffon.

APEDIA; Little Baboon. Thumb close to the fingers; nails oblong, thumb-nails rounded; haunches covered. This is an inhabitant of India. The nails are oblong and compressed, except the thumb and great toe-nails, which resemble those of a man; the tail is scarcely an inch long; the face is brown, with a few scattered hairs.

SRHINX; Great Baboon. Mouth with whiskers; nails acuminate; haunches naked. This is found in the island of Borneo; it is lascivious, robust, and fierce; it feeds on

fruits and seeds; it makes great havoc in the produce of cultivated lands. The head is oblong, resembling that of a dog, but more obtuse; the neck is long; the tail is short and erect; the haunches red, edged with purple; it is from three to four feet high in its fitting posture. It is extremely strong and muscular in its upper parts, and slender towards the middle. It is, says Dr. Shaw, ferocious in its manners, and its appearance is at once grotesque and formidable. The region surrounding the tail to a considerable distance on each side is bare and callous. It is a native of Borneo, and inhabits the hotter parts of Africa.

**MORMON; Tufted Ape.** Beard thin; cheeks tumid, naked, blue, obliquely furrowed; haunches naked, red. It inhabits India. This, in an upright posture, is full five feet high. It is the most remarkable of the whole genus for brilliancy and variety of colour. The general tinge is a rich and very deep yellowish-brown; the hairs, if viewed near, are speckled with yellow and black. The form of the face is long, with the snout ending somewhat abruptly; the whole length of the nose, down the middle, is of a deep blood-red; but the parts on each side are of a fine violet-blue, marked by several oblique furrows. The remainder of the face is of a pale whitish-yellow. On the top of the front the hair rises, in a remarkable manner, into a pointed form, and beneath the chin is a pointed beard of a light orange-yellow. Round the back of the neck the hair is much longer than in other parts, and inclines downwards and forwards, somewhat in the manner of a wreath or tippet. The hands and feet are of a dusky colour, and are furnished with broad pointed claws. It is a native of the interior parts of Africa, but has been found in India.

**MAIMON; Ribbed-nose Ape.** Beard thin; cheeks blue, striate; haunches naked. It inhabits Guinea; weeps and groans like men, when in trouble; it is libidinous, ugly, and disgusting. The general likeness which it bears to the former species is such as to give the idea of the same animal in a less advanced state of growth, and with less brilliant colours. The chin is furnished with a small sharp-pointed beard of a pale orange-colour. The feet are armed with claws, and have no flattened nails. This baboon is not uncommon in exhibitions of animals.

**PORCARTA; Hog Baboon.** The head of this species resembles that of a hog; the snout is naked; the body of an olive-brown; the haunches are covered, and the nails are acuminate. It is said to be three feet six inches in length; its colour is of a deep olive-brown; the face is large and black; the nose is truncated at the end, somewhat like that of a hog.

**SYLVATICA; Wood Baboon.** Face, hands, and feet naked, black, smooth; nails white. It inhabits Guinea, and is about three feet high. It is of a robust frame. Its general colour is ferruginous, owing to the alternate blackish-brown rings with which every hair is marked, and which give a kind of speckled appearance to the whole. The nails on the hands are longish, but rounded at their extremities; those on the toes longer and acuminate. The space on each side the tail is large, bare and red: the tail is about three inches long.

**VARIEGATA; Yellow Baboon.** This species is of a bright yellow colour mixed with black; the face is long, black, naked; the hands are covered on the back with hair. It very much resembles the *sylvatica*, and is found in Africa. Above the eyes are several long dusky hairs: it is about two feet high.

**CINEREA; Cinereous Baboon.** The face of this is dusky; the beard is of a pale brown; the crown is variegated with

yellow; the body is cinereous. It is found in divers parts of Africa, and is about two feet high.

**LIVEA; Blue-faced Baboon.** The face of this species is blueish; it has two broad flat fore-teeth; the beard is pale brown. Over the eyes are long hairs; the ears with a tuft of hair behind each; the hair is black mixed with cinereous and rusty-brown: this is three feet high.

**PLATYPYGOS; Brown Baboon.** The face is of a dirty white, surrounded with short straight hairs. The upper part of the body is brown, under cinereous; tail tapering, almost bare; it is naked beneath. This species, according to La Cépède, is the same with the long-legged baboon described in the additions to Buffon. The figure there given is the same with that in Mr. Pennant's *Quadrupeds*. The distinguishing character of the animal seems to be the great length of its limbs.

**CRISTATA; Crested Baboon.** In this species the hair on the crown of the head and cheeks is long and dishevelled. The body is covered with long black hair; the breast is whitish; the face, hands, and feet are black and naked; the tail is tapering, and about seven inches long; the animal is two feet high. It is an inhabitant of India.

**Section C. MONKIES with long Tails, that are not prehensile: the Cheeks are pouches, and the Haunches naked.**

**CYNOSURUS; Dog-tailed Monkey.** It has no beard; the face is long; the forehead foxy; it has a whitish band over the eyes; male genitals coloured; the nails are convex. It is about two feet high, and is said to be faithless, restless, and lascivious. The face of this animal appears uncommonly mild and placid. It was very fond of snuff, which it would occasionally rub over its body in a very ridiculous style.

**HAMADRYAN; Tartarian Monkey.** This is described as cinereous; the ears are hairy; the nails sharpish; the haunches red. It inhabits Africa, is fierce and very singular in its appearance. The face is prominent; the nose smooth and red; the ears are pointed, and almost hidden in fur; the hair on the sides of the head, and as far as the waist, long and shaggy; the nails of the fingers are flat, those of the toes acute and narrow: it is about five feet high. There is a variety, of which above the fore-head is prominent, terminating in a ridge. It inhabit the Cape of Good Hope, is very gregarious, pillages gardens, and is watchful of surprize; the head is large; the nose is long and thick; the ears short; the crown is covered with long upright hairs; the body is rough and hairy; the tail is about half the length of the body, arched at the end; the nails are flat and rounded; the haunches are red, and the animal is from four to five feet high.

**VETER; Lowando.** The beard is black; the body is white. There is a variety with a white beard. It is found in Ceylon, is wild, ferocious, and mischievous. The tusks of this species are long and large; the head is surrounded with a broad mane; the body is long and tapering: it is between three and four feet high.

**SILIENS; Wanderu.** The beard of this animal is long and black; and the body is black. There are three other varieties of this species. The first has a bushy beard, is found in Ceylon, and other parts of India. The second is of a jet black colour; the beard is white, and very long; it inhabits Guinea, and is about two feet high. The third has a white beard, which is triangular, short, and pointed, extending on each side beyond the ears. It inhabits Ceylon, is harmless, and lives in the woods; it feeds on leaves and buds, and is easily tamed; the body is black; the face and hands

hands are purple; the tail is long, ending in a dirty white tuft.

**FAUNUS; Malbrouck.** This species is bearded; the tail is bushy at the end; it is an inhabitant of Bengal; the face is grey; the eyes are large; the eye-lids are flesh-coloured; forehead with a grey band, instead of eye-brows; the ears are large, thin, flesh-coloured; body is blackish; the breast and belly are white; the beard is hoary and pointed: it is scarcely a foot high.

**CYNOMOLGUS; Long-tailed, beardless monkey,** with callosities behind, rising bifid nostrils, and arched tail. This by Pennant is called the Hare-lipped monkey, who includes in the species the cynomolgus and cynocephalus of Linnæus. It is of a thick clumsy form, resembling the Barbary ape, except in having a long tail. It varies in size very greatly; some specimens scarcely exceed the size of a cat, while others are full as large as a grey-hound. The colour also is various, being sometimes olive-brown, at other times grey-brown. The head is large; the eyes are small; the nose thick, flat, and wrinkled; on each side the tail is a bare space; the under sides of the body, and the insides of the limbs, of a light ash-colour. It is a native of Guinea and Angola. The nostrils are divided like those of a hare.

**CYNOCEPHALUS; Dog Monkey.** This has no beard; it is of a yellowish colour, has a projecting mouth, a straight tail, and bald haunches. It is found in divers parts of Africa, and resembles the *S. inuus*, except that it has a tail.

**DIANA; Spotted Monkey.** This species is bearded; the forehead is projecting; the beard is pointed. This is described by Mr. Pennant as of a middling size, and of a reddish colour on the upper parts, as if fringed, and marked with white specks; the belly and chin are whitish; the tail is long. According to Linnæus, it is of the size of a large cat, and is black, spotted with white; the hind part of the back is ferruginous; the face is black; from the top of the nose is a white line, passing over each eye to the ears in an arched direction.

**SABÆA; Green Monkey.** This animal has no beard; it is of a yellowish-green colour; the face is black; the tail is grey; the haunches naked. It inhabits the Cape de Verd islands, the Cape of Good Hope, and other neighbouring countries. The body in the upper parts is a mixture of grey, green, and yellowish; throat, breast, belly, and thighs are white; the hairs are long and reversed; the eye-brows are black and bristly; the tail is straight, as long as the body, and hoary; the feet are cinereous; the nails round, those of the hands ovate. It is about the size of a cat.

**CEPIUS; Moustache.** Tailed; cheeks bearded; crown yellowish; feet black; tail rusty at the point. It inhabits Guinea. The body above is brown; beneath it is of a blueish-white; the head with white erect hairs; eye-brows with a white transverse arch; upper eye-lids white; hair on the cheeks standing out; the mouth is blueish; under the ears are two large tufts of yellow hairs, like moustachios.

**ÆTHIOPS; White eye-lidded Monkey.** This is without tail and beard; the fore-top is white, erect; the arch of the forehead is white. There is a variety, of which the neck and cheeks are surrounded with a broad collar of white hair. It is found in Madagascar. Its face is thick and broad; the eyes are surrounded by a prominent ring; the eye-lids are naked, very white; the ears are black, almost naked; the tail is arched, covered with long bushy hair: it is about eighteen inches high.

**AYGULA; Egret.** This is tailed, the beard is scanty; the colour is grey; crown with an erect tuft of hair reversed

longitudinally. It inhabits India and Java. The body is a good deal like that of a wolf; the throat, breast, and belly whitish; the tail is longer than the body, cinereous, and tapering; the face is flattish, whitish, naked; the nose is depressed, short, and distant from the mouth, with a double furrow on the upper lip; the cheeks are a little bearded; the hairs are turned back; the eye-brows are gibbous, bristly, prominent; the feet are black, semi-palmate; the nails of the thumbs and great toes are rounded, the rest oblong; the ears are pointed; an arched future from the ears towards the eyes and back to the base of the lower jaw, and a longitudinal seam on the fore-arm. There is a variety that has a rounder head; the face is less black; the body is of a paler brown.

**NICTITANS.** Tailed, beardless, black, sprinkled with pale spots; the nose is white; the thumb very short; the haunches are covered. This is called the Nodding monkey. There is a variety of it having a long white beard. It inhabits Guinea, is playful, and continually nodding its head. The face is hairy; the mouth short; the orbits naked; the irids of a pale yellow; the hair is black, with a few pale rings; lips and chin whitish; the tail is straight, cylindrical, longer than the body; the thumb is not longer than the first joint of the fore-finger.

**SINICA; Chinese Monkey.** Tailed, beardless; fore-top horizontally placed, and shading the whole head. There is a fore-top erect, having the appearance of a round black bonnet; the body is brown; the legs and arms black. The species is found in Bengal, and the variety in India. The tail is longer than the body; the nails of the thumbs and great toes are rounded, the rest oblong; the upper parts of the body are pale brown, mixed with yellow; the lower whitish. It is about the size of a cat.

**NEMÆUS; Cochinchina Monkey.** This is without tail and beard; the cheeks are bearded; and the tail white. It inhabits, as its trivial name imports, Cochinchina; also Madagascar, and other places. The face and ears are of a light red; the forehead is marked with a double brown band, covered with black hair; the hair surrounding the face is whitish, mixed with yellow; neck, on the upper part, with a wreath of the same colour as that of the forehead; the shoulders and upper parts of the arms black; hands and groin whitish; thighs on the upper part and toes black; feet to the knees brown; it is from two to four feet high. From this species is procured the bezoar of the ape.

**MONA; Varied Monkey.** This species is tailed and bearded; it has a prominent whitish-grey semi-lunar arch over the eye-brows. It inhabits Morocco, and the warmer parts of Asia; is gentle, docile, and patient of cold. The head is small and round; the face is bright, and of a tawny brown; the hair on the crown is yellow, mixed with black; it has a dark band from the eyes to the ears, and to the shoulders and arms; tail is greyish-brown; the rump is marked with two white spots on each side. It is eighteen inches high.

**RUBRA; Red Monkey.** This species is tailed and bearded; the cheeks are bearded; the crown, the back, and the tail, are of a deep blood-red. There are two other varieties; the first has a yellow beard; the band over the eyes is black: the second has a white beard; the band over the eyes is white. This is found in Senegal, Congo, and other hot parts of Africa. The crown is flat; the body and legs are long; the hair on the upper parts is of a bright red, beneath it is of a yellow-grey; over the eyes to the ears is a band. One variety is black; and another is white;

white; the tail is longer than the body. It is from eighteen inches to two feet in height.

**TALAPOIN**; This is tailed and bearded; the cheeks are bearded; the ears, nose, and soles of the feet black. It inhabits India. The body is of a brownish-green, and elegant. A variety is of a black colour. The head is roundish; the face is tawny, with a few black hairs; the ears are like those on the human subject; the breast, belly, and thighs on the inside are of a dusky flesh-colour; it is extremely gentle and playful, and is of the size of a cat.

**PETAURISTA**; Agile Monkey. This animal is tailed and bearded; its back, upper part of the tail, anterior parts of the legs, dark olive; its face is black, and the nose is marked with a triangular white spot. It inhabits Guinea, and is, like the last, gentle and docile; it is little more than a foot high, though the tail is twenty inches long.

**MAURA**; Negro Monkey. This is tailed and bearded; the cheeks, whole face, except the region extending from the eyes to the tip of the nose, are bearded; the body is of a reddish-brown. It inhabits Ceylon and Guinea, is active and gentle. The tail is longer than the body; the face is tawny and flesh-coloured; the feet and hands are black, naked, and soft. In a fitting posture it is only about seven inches high.

**ROLOWA**. This species is tailed and bearded; the head, back, and outside of the hands and feet, are black; the inside, belly, and circular beard, enclosing a triangular face, are white. This is an inhabitant of Guinea; is gentle and docile. The beard is long and forked: it is eighteen inches long, with a tail of the same length.

**NASUA**. This has no beard; the face is long, slender, naked, flesh-coloured; the nose is projecting. It inhabits Africa, and is good-tempered. The head is covered with thick longish hair, falling backwards; the ears are small, pointed, and almost naked; the hair on the upper parts and limbs is long, rusty-brown mixed with black; on the breast and belly it is ash-coloured; the tail is very long: in a fitting posture it is only two feet high.

**LUTEOLA**; Yellow Monkey. In this species the tusks are very large; the ears also are large, black, naked; the cheeks have long pale-yellow locks reverted. It inhabits Guinea. The crown, upper parts of the body, arms, and thighs, are of an ash-colour, mixed with yellow; the lower parts are cinereous; the face is black, with long hairs over the eyes; the throat and breast are of a yellowish-white; the hair is coarse; the tail is as long as the body, and it is about the size of a fox.

**FULVA**; Tawny Monkey. This has tusks in the lower jaw, which are long; the face is long and of a flesh-colour; the nose is flattish. The hair on the upper part of the body is pale tawny, though cinereous at the roots; the hind part of the back is of an orange-colour; the legs are cinereous and the belly white. It is of the size of a cat. It inhabits India. Pennant, who seems to be the only describer of this animal, took the description from one in an exhibition in London, which was an extremely ill-tempered animal. It is said to vary with a black face, and long black hairs on the cheeks; the body is of a dull pale-green; the limbs are grey and the tail dusky.

**VRIDENS**. The face of this is black; the cheeks have long black hairs; the body is of a pale-green; the limbs are grey; the tail is dusky. It is thought by some naturalists not to be a distinct species, but a variety of the *S. fulva*.

**HIRCINA**. Face naked, blue, obliquely ribbed; the beard is long, and like that of a goat; the tail is long, and the body of a deep brown.

**REGALIS**. To this species there is no thumb; the head, cheeks, throat, and shoulders, are covered with long coarse flowing hairs. It inhabits the forests of Sierra Leona. The head is small; the face is short, black, naked; the toes are long and slender; the nails are narrow and pointed; the tail is long, covered with snow-white hairs, and a tuft at the end; the body and limbs are slender; it is three feet high. The skin of this animal is, by the natives, made into pouches and gun-cases.

**BODIA**; Bay Monkey. This has no thumbs; the tail is long, slender, and black; the body and limbs are slender. It inhabits Sierra Leona. The crown is black; the back is of a deep bay; limbs on the outside black; cheeks, under parts of the body, and legs, of a bright bay.

**FUSCA**; Brown Monkey. The tail shorter than the body, alternately annulate with dark and light-brown. The face is flat; the cheeks and forehead are covered with long hairs; the body above is of a tawny-brown, belly cinereous; hands black and naked.

Section D. *Tails prehensile; no Cheek-pouches; Haunches covered. These are denominated*

## SAPAJOUS.

**BEEZEBUL**, or Bearded Black Monkey. By Pennant it is denominated the Preacher monkey. It is tailed, bearded, and black. The tail at the tip and feet are brown. It inhabits South America; wanders in herds at night, and howls hideously; it is exceedingly fierce; the beard is round and black; the hair long, black, and smooth. For the account given of this animal by Maregrave, see **BEEZEBUL**.

**SEVICULUS**; Old Man of the Woods. This is tailed and bearded; the colour is red. The body is uniformly of a dirty red; it has a mouth like that of the human subject, placed in the anterior part of the face; the chin is prominent, and it is as large as a middling-sized calf. This, which by some has been regarded as a variety of the *S. beezebul*, is denominated by Mr. Pennant the Royal monkey. There were formerly two in the Leverian museum, which were probably young, being of the size of a squirrel. They were entirely of a very bright ferruginous or reddish chestnut colour, with the face naked and black, surrounded on the lower parts by a straggling beard of black hairs, and the tail was strongly prehensile. This species is common in Cayenne, but very rare in Brazil: on the contrary, the former species is very common in Brazil, but is not found in Guiana. Both species have the same voice and manners. The following is an interesting description given by an observer, who had seen and kept these animals at Cayenne.

“The Allouates, or Howlers, inhabit the moist forests, in the neighbourhood of waters or marshes. They are commonly found in the woody islets of large flooded savannahs, and never on the mountains of the interior of Guiana. They go in small numbers, often in pairs, and sometimes singly. The cry, or rather horrible rattling scream, which they make, may well inspire terror; and seems as if the forests contained the united howlings of all its savage inhabitants together. It is commonly in the morning and evening that they make this clamour: they also repeat it in the course of the day, and sometimes in the night. The sound is so strong and varied, that one often imagines it produced by several of the animals at once, and is surprised to find only two or three, and sometimes only one. The allouate seldom lives long in a state of captivity: it in a manner loses its voice, or at least does not exert it in the same manner as when wild. The male is larger than the female, which latter always carries her young on her back

“ Nothing is more difficult than to kill one of these animals. It is necessary to fire several times in order to succeed, and as long as the least life remains, and sometimes even after death, they remain clinging to the branches by the hands and tail. The sportsman is often chagrined at having lost his time and ammunition for such wretched game; for, in spite of the testimony of some travellers, the flesh is not at all good; it is almost always excessively tough, and is, therefore, excluded from all tables: it is merely the want of other food that can recommend it to needy inhabitants and travellers.”

**PANISCUS.** This is the four-fingered monkey of Pennant; it is tailed, black, beardless, and without a thumb, hence its trivial name. This animal is distinguished by the gracility of its body and limbs; its uniform black colour, except on the face, which is of a dark flesh-colour; and by want of thumbs on the fore-feet, instead of which are very small projections or appendices. It is one of the most active and lively of animals, and is, besides, of a gentle and tractable disposition in a state of confinement. It inhabits the woods of South America; associating in great multitudes, affailing such travellers as pass through their haunts with an infinite number of sportive and mischievous gambols, chattering, and throwing down dry sticks, fwinging by their tails from the boughs, and endeavouring to intimidate the challengers by a variety of menacing gestures. This is the Coaita of Buffon.

**EXQUINA.** Bearded; back variegated with black and yellow; throat and belly white. It inhabits South America. In size and disposition it resembles the *S. paniscus*.

**TREPIDA.** Tailed, but without a beard; the fore-top is erect; hands and feet are blue; the tail is hairy. A variety has the hair round the face grey; it is brownish-yellow on the body. It inhabits Surinam, is nimble, dextrous, and amusing, and about twelve inches high. The body is brown, beneath it is rusty; the hair of the head is formed into a black erect hemispherical tuft; the tail is hairy; the nails are rounded; the face and ears downy and flesh-coloured; the eyes are approximate chefnut.

**FATUELLUS.** The horned fapajou is tailless and without beard; two tufts on the head resembling horns. It is found in several parts of South America, is harmless and gentle. The face, sides, belly, and front part of the thighs, are brown; the crown, the middle of the back, tail and feet, and hind part of the thighs, are black; the nails are long and blunt; the tail is spiral.

**APELLA;** Brown Sapajou, or Sajou of Buffon. This also is without tail and beard; the body is brown; the feet are black.

**CAPUCINA;** Capuchin Monkey, or Sai of Buffon, and Weeper of Pennant. This has no beard; the skin is brown; the hair and limbs are black; the tail is shaggy and the haunches are covered. There is a variety of this, of which the hair on the breast, throat, round the ears, and cheeks, is white. The face is sometimes black, sometimes flesh-coloured on the forehead; the tusks are approximate; the nose is carinate towards the eyes; a black varicose retractile wrinkle just under the hair of the forehead; the tail is long, always curved, and covered with long shaggy hair; it is of the size of a cat. It inhabits divers parts of South America; it is mild, docile, timid; walks on its heels, and does not skip. It has a crying wailing voice, and repels its enemies by horrid howlings; it shrieks sometimes like a cricket. When made angry it will yelp like a puppy; it carries the tail spirally rolled up, which is often coiled round the neck: it smells of musk.

**SCIUREA;** Orange Monkey, or Saimiri of Buffon. Beardless; the hind part of the head is prominent; the

nails of the four smaller toes unguulate; the haunches are covered. The body is of a greenish-grey, under parts whitish; the legs and arms are rusty; the tail is shaggy, black at the tip, and twice as long as the body; the nails of the thumbs and great toes are rounded; the face of a blueish-brown; the eye-brows are bristly; the ears are scantily covered with whitish hairs; it is of the size of a squirrel. It is found in South America; is pleasant in its disposition, beautiful, and graceful; it rests by lying on its belly. It looks full in the face of such as speak to it. It is impatient of European climates.

**MORTA.** Without beard, but it has a tail; it is of a chefnut colour; the face is brown; the tail is naked and fealy. It is found in different parts of America. It differs from the *S. sciurea* only in being less, and on that account it has been supposed to be of the same species.

**SYRICHTA.** This is without tail and beard; the mouth and eye-brows are covered with long hairs. This is an obscure and doubtful species.

**VARIEGATA.** The hair on the sides and back is mixed with orange and black. It inhabits Antigua, is lively, docile, and full of amusing tricks.

**Section E.** *Monkeys with Tails that are not prehensile; that have no Cheek-pouches; the Haunches are covered. These are denominated*

## SAGOINS.

**PITHECIA;** Fox-tailed Monkey. Tailed, but without beard; the hairs of the body are long, and black at the tips; the tail is black, and very shaggy. It inhabits South America; is very amusing, and easily tamed. It is entirely of a dusky brown colour, with a slight ferruginous cast, except on the head and face. This is the *Saki* of Buffon.

**JACCHUS;** Striated Monkey, or Ouilititi of Buffon, and Sanglin or Cagui minor of Edwards. This is tailed; its ears are hairy, broad; tail curved, very hairy; nails subulate, those of the thumbs and great toes are rounded. There is a variety, which is of a yellowish colour, smelling like musk. It inhabits Brazil; is active, restless, climbing like a squirrel; it feeds on insects, fruits, milk, bread, and small birds; it gnaws the bark of trees, is untameable, biting, tormenting cats by fixing under their bellies, and emits a hissing cry.

**ŒDIPUS;** Red-tailed Monkey. This is tailed and beardless; locks hanging; the tail is red; nails subulate. The body is grey, underneath it is white; the head has long white hanging locks; its face is black, and it has a few white hairs behind the ears; a wart on each cheek; the irids are rusty; the ears are roundish, black, and naked; nails subulate, except the thumb; the tail is twice as long as the body, and is a little hairy, black, red at the base; the region of the anus is red. It inhabits South America, is active, brisk, imitating the lion in its gestures. It is something less than the *S. jacchus*; it smells of musk, and the voice resembles that of a mouse.

**ROSALIA;** Silky Monkey. Tailed; beardless; the head is hairy; circumference of the face and feet are red; the nails are subulate. This species derives its trivial name from the appearance of its hair, which is very fine, soft, long, and of a bright yellow colour, resembling yellow silk. Round the face the hair is much longer than in other parts, so as to form a large mane, like that of a lion; near the face this mane is of a reddish colour, and it grows paler as it recedes from the cheeks; the face itself is of a dusky purple; the ears are round and naked; the hands and feet are also naked, and of the same dull purple colour as the face; the claws are small and sharp; the tail is very long,  
and

and rather bushy at the extremity. It is a native of Guiana, and is a lively, active species, and gentle in a state of confinement. This is the Marikina of Buffon.

**MIDAS**; Tamarin. This species is tailless; beardless; the upper lip is cleft; the ears are square and naked; the nails are subulate. The tamarin, or great-eared monkey, is about the size of a squirrel; it is coal-black, except on the lower part of the back, which is of a reddish colour, and on the hands and feet, which are orange-coloured; the face is naked and flesh-coloured; the ears are very large, naked, of a squarish form, and of a dusky flesh-colour; the tail is very long and black. It inhabits the hotter parts of South America. The claws are small and sharp. It sometimes varies in having the face black, instead of flesh-coloured.

**SIMIA Marina**, the *Sea-Ape*, in *Ichthyology*, a name used by Bellonius, and some other authors, for the fish called *vulpes marina*, a kind of shark, remarkable for its long tail, from which probably it had both one and the other of these names. See *Sea-Fox*.

**SIMICON**, in *Antiquity*, an ancient musical instrument of the stringed kind, with thirty-five strings. Mem. de l'Acad. Inscript. vol. v. p. 168.

**SIMICUS**, in *Biography*, an ancient Greek musician, said to have been a great improver of music. He lived after Homer, and has the reputation of having invented the instrument above-mentioned; but Plutarch says, that the ancient Fables attribute this instrument to Pytoelclus. He also informs us, that the Argians fined the first person that used it; but does not tell us how it was used, or whether there was a complete scale for every one of the genera: 35 notes in the diatonic scale would mount it above the additional compass of modern piano fortes.

According to Pliny, Simicus added an eighth string to the lyre of Mercury. Boethius says that it was Lychaon of Samos; but Nichomachus gives it to Pythagoras. So many claimants to the same inventions destroy all evidence to whom they belong.

**SIMILAR**, in *Arithmetic* and *Geometry*, the same with *like*.

Those things are said to be similar, or like, which cannot be distinguished but by their compresence; that is, either by immediately applying the one to the other, or some other third to them both. So that there is nothing found in one of the similar things, but is equally found in the other.

Thus, if you note all the things in A, which may be discerned and conceived, without assuming any other; and, in like manner, note all the things in B, which may be thus conceived, and A be similar to B; all things in A will be the same with those in B.

Since a quantity cannot be understood otherwise, than by assuming some other quantity to which it may be referred; similar things, notwithstanding their similitude, may differ in quantity: and since, in similar things, there is nothing in which they differ, beside the quantity; quantity itself is the internal difference of similar things.

In mathematics, similar parts, as A, a, have the same ratio to their wholes B, b; and if the wholes have the same ratio to the parts, the parts are similar. Similar parts A, a, are to each other as their wholes B, b. See **PART**.

**SIMILAR Angles** are also equal angles. See **SOLID Angle**.

**SIMILAR Rectangles** are those which have their sides about the angles proportional.

Hence, 1°, all squares must be similar rectangles. 2°. All similar rectangles are to each other as the squares of their homologous sides.

**SIMILAR Triangles** are such as have all their three angles respectively equal to each other, and the sides about the equal angles proportional. See **TRIANGLE**.

Hence, 1°, since in all triangles mutually equiangular, the corresponding sides containing the equal angles are proportional, equiangular triangles are similar to each other. And if two triangles have their sides respectively proportional, those triangles are equiangular.

2°. All similar triangles are to each other, as the squares of their homologous sides.

In similar triangles, and parallelograms, the altitudes are proportional to the homologous sides, and the bases are cut proportionably by those sides.

**SIMILAR Polygons** are those whose angles are severally equal, and the sides about those angles proportional.

And the like of other similar rectilinear figures.

Hence, all similar polygons are, to each other, as the squares of the homologous sides.

In all similar figures, the homologous angles are equal, and the homologous sides proportional. All regular figures, and similar irregular ones, are in a duplicate ratio of their homologous sides. Circles, and similar figures, inscribed in them, are, to each other, as the squares of the diameters.

**SIMILAR Arches**. See **ARCH**.

**SIMILAR Curves**, in *Geometry*. The similarity of curvilinear figures may be derived from that of rectilinear figures, that are always similarly described in them; or, we may comprehend all sorts of similar figures, planes, or solids, in this general definition. Figures are similar, when they may be supposed to be placed in such a manner, that any right line being drawn from any determined point to the terms that bound them, the parts of the right line, intercepted betwixt that point and those terms, are always in one constant ratio to each other.

Thus the figures ASD, aSd (*Plate XIII. Geometry, fig. 14.*) are similar, when any line SP being drawn always from the same point S, meeting AD in P, and ad in p, the ratio of SP to Sp is invariable. It is manifest, that the rectilinear inscribed figures, apdS, APDS, are similar in this case, according to the definition of such figures given in Euclid's Elements, book vi. See MacLaurin's Fluxions, art. 122.

When the similar figures are in the situation here described, they are also similarly situated, and all their homologous lines are either placed upon one another, or parallel.

**SIMILAR Segments of Circles** are such as contain equal angles. See **SEGMENT**.

**SIMILAR Conic Sections** are those where the ordinates to a diameter in one are proportional to the correspondent ordinates to the similar diameter in the other; and where the parts of similar diameters between the vertices and ordinates in each section are similar.

The same definition also agrees to similar segments of conic sections.

**SIMILAR Diameters of two Conic Sections**. When the diameters in two conic sections make the same angles with their ordinates, they are sometimes said to be similar.

**SIMILAR Solids**. See **LIKE Solid Figures**.

**SIMILAR Bodies**, in *Natural Philosophy*, such as have their particles of the same kind or nature one with another.

**SIMILAR Plain Numbers** are those which may be ranged into similar rectangles, *i. e.* into rectangles whose sides are proportional; as 6 multiplied by 2, and 12 by 4, the product of one of which is 12, and the other 48, are similar numbers.

**SIMILAR Solid Numbers** are those, whose little cubes may

be so ranged, as to make similar and rectangular parallel-epipeds.

**SIMILAR Animals.** We have a treatise by Dr. Martin, wherein he treats of the laws and proportions of the motions and forces of the solids and fluids of animals, of however different magnitudes, which are supposed of similar make and constitution. See *Tractat. de Similibus Animalibus*.

**SIMILAR Disease,** in *Medicine*, denotes a disease of some simple, solid part of the body: as of a fibre, with regard to its tension, or flaccidity; of a membrane; a nervous canal, or the like. See **DISEASE**.

**SIMILAR Parts,** in *Anatomy*, are those parts of the body, which, at first sight, appear to consist of like parts, or parts of the same nature, texture, and formation.

Of these we usually reckon ten, *viz.* the bones, cartilages, ligaments, membranes, fibres, nerves, arteries, veins, flesh, and skin; each of which see under its proper article.

Dr. Grew, in his *Anatomy of Plants*, observes, that these have likewise their similar and organical parts.

**SIMILE**, or **SIMILITUDE**, in *Rhetoric*, a comparison of two things, which, though different in other respects, yet agree in some one. *As, He shall be like a tree planted by the water-side, &c.*; so that in every similitude three things are requisite; two things that are compared together; and a third, in which the likenesses or similitude between them consists.

The difference between a *simile* and a *comparison* consists in this, that simile properly belongs to what we call the quality of the thing, and the comparison to the quantity.

And the difference between a metaphor and similitude consists in this, that a metaphor has not those signs of comparison which are expressed in a similitude. See **METAPHOR** and **PARABLE**.

**SIMILITUDE**, in *Arithmetic, Geometry, &c.* denotes the relation of two things similar to each other, or which are only distinguishable by preference.

The notion of similitude, which now makes some figure in geometry, &c. is owing to M. Leibnitz: it will be rendered easy by the following instance. Suppose two watches perfectly alike, the one belonging to Caius, the other to Gracchus. If now Caius pull out his watch in presence of Gracchus, the latter will be surpris'd, and fancy it his own; but he will perceive it different from his own, upon pulling out his own; that is, Gracchus distinguishes Caius's watch from his own by their preference; or, by applying the one immediately to the other.

Euclid, and after him most other authors, demonstrate every thing in geometry from the sole principle of congruity. Wolfius, in lieu of it, substitutes that of similitude; which, he tells us, was communicated to him by M. Leibnitz, and which he finds of very considerable use in geometry, as serving to demonstrate many things directly, which are only demonstrable from the principle of congruity by an ambages.

**SIMILOR** is a name given to an alloy of red copper and zinc, made in the best proportions to imitate the colour of gold. See **GOLD-coloured Metal**.

**SIMIRA**, in *Botany*, *Aubl. Guian.* 170. t. 65. *Juss.* 205, the Guiana name of a shrub, belonging to the natural order of *Rubiaceæ*, and the *Pentandria Monogynia* of the Linnæan system, but of whose generic characters nothing has yet been precisely settled. It seems very near akin to *Psychotria*, or to *Stephanium*; see those articles.

**SIMITAR**, or **SCIMITAR**, in *War*, a crooked or falcated sword, with a convex edge; not now used

**SIMLEE**, in *Geography*, a town of Hindoostan, in *Guzerat*; 17 miles N. of Champaneer.

**SIMLER**, **JOSIAS**, in *Biography*, was born at Cappel, in Switzerland, in the year 1530. He was minister at Zurich, and a professor in the school of that town. He wrote several controversial works against some of the heretical sects, as they were esteemed, and denominated by him. He taught mathematics with great reputation, illustrating his lessons by various machines of his own invention. Of his writings the principal were "*De Helvetiorum Republica*," which contained an account of the original constitution of the Swiss confederacy; "*Vallesiæ Descriptio*," being an account of the Valais, and the adjacent alps; and an abridgement of the *Bibliotheca* of Conrad Gesner, with the life of that distinguished person. In this last work he has not only given a good summary of the original, but has rendered it more complete, by the addition of a number of books. He died at Zurich in 1576, at the time when he was preparing a history of his native country.

**SIMLY**, in *Geography*, a town of Hindoostan, in *Orissa*; 15 miles N.W. of Boad.

**SIMMEN**, or **SIBEN**, a river of Switzerland, which rises in the mountains between the Valais and the canton of Berne, and runs into the lake of Thun; 4 miles N.N.W. of Spiez. The valley through which this lake runs, and which has on each side stupendous rocks, is called "*Simmenthal*," and is divided by it into the Upper and Lower. The inhabitants of some few parts of this valley sow rye, oats, or wheat; but they derive great profit from their grass, which is very rich, and they also breed a great number of cattle, from which they make butter and cheese. The latter sort of cheese, called "*Saan*" cheese, is much esteemed abroad, being made wholly of cream; and of the common cheese, France and other countries purchase considerable quantities. Most of the inhabitants, instead of bread, eat the second sort of cheese, with thin barley cakes; and the principal food of the commonalty is potatoes, and their drink is milk or whey.

**SIMMERN**, a town of France, and principal place of a district, in the department of the Rhine and Moselle, late capital of a duchy of the same name, veiled in the electorate of the Rhine. The place contains 1469, and the canton 8361 inhabitants, in 31 communes. The territory of the district contains 1687½ kilometres; 26 miles S.S.W. of Coblentz.—Also, a river of France, which passes by Simmern, Gemunden, &c. and runs into the Nahe; 3 miles E. of Kirn.

**SIMMIA CHUMBA**, a town of Bengal; 16 miles S. of Palamow.

**SIMMONS'S ISLAND**, a small island on the coast of South Carolina. N. lat. 32° 38'. W. long. 80° 10'.

**SIMO**, a town of Sweden, in East Bothnia, on a river of the same name, which runs into the gulf of Bothnia; 80 miles E. of Ulea.

**SIMOGU**, a town of Hindoostan, in Mysore, on the Tumbadra; 93 miles W. of Seringapatam. N. lat. 13° 21'. E. long. 75° 40'.

**SIMOJOSIKI**, one of the smaller Japanese islands, near the S.W. coast of Ximo. N. lat. 31° 50'. E. long. 132° 8'.

**SIMOIS**, in *Ancient and Modern Geography*, a river of Asia Minor, in the Lesser Phrygia, the source of which was in mount Ida, and which discharged itself into the Xanthus, or the Scamander, according to Pliny. The source of the Simois lies S.W. of Cotylus; it flows nearly to the W., traverses a space of from twelve to fifteen leagues; receives the Andrius above Inchavi, and several other rivulets, and discharges

discharges itself into the Hellespont, half a league to the N.N.E. of cape Sigeum. This stream is not now sufficiently considerable to deserve the name of river; it is rather

torrent swelled by the rains, at the end of the autumn, in winter, and in the spring, or by the sudden melting of the snow, which falls on mount Ida and Cotylus. Its bed is tolerably wide, but its waters are seldom abundant, and in summer it is almost dry, since a pacha has turned aside the stream of the Scamander, and directed its waters into the Ægean sea. See SCAMANDER.

SIMON, in *Biography*, a name that frequently occurs in ancient history: some of the principal persons who sustained this appellation are as follow; *viz.*

SIMON *the Just*, high-priest of the Jews, was the son and successor of Onias I. and promoted to this dignity A.M. 3702, or 3703. He died A.M. 3711, before A.D. 293. —Also, SIMON, son of Onias II., advanced to the high-priesthood A.M. 3805, B.C. 199. In his time, A.M. 3787, Ptolemy Philopater came to Jerusalem, and attempted to enter the interior parts of the temple, where no one but the high-priest ought to have entered. Simon opposed him, and prevented his design. He is supposed to have been the person to whom the book of Ecclesiasticus gives a high encomium. His successor was Onias III.

SIMON *Maccabæus*, furnished *Thaffi*, the son of Mattathias, and brother of Judas and Jonathan, was chief, prince, and pontiff of the Jews from A.M. 3860 to 3869, B.C. 135. He gave proofs of his valour in the battle between Judas Maccabæus and Nicanor (2 Macc. viii. 22, 23.), and on another occasion (2 Macc. xiv. 17.) In consequence of his judgment and valour, which were signalized in a variety of ways, he was made governor of the whole coast of the Mediterranean sea, from Tyre to the frontiers of Egypt, by the young king Antiochus Theos. He also took Bethfura and Joppa, and built Adida, in the plain called Sephela. When Tryphon had slain Jonathan and his two sons, and having marched into Syria, put to death the young king Antiochus, and usurped his kingdom, Simon supported his competitor, Demetrius Nicator, who, at his request, confirmed the ancient franchises of Judea, and granted freedom from tribute. After this he took Gaza, and the Syrians that were in the citadel of Jerusalem capitulated to him. His administration was singularly prudent, and it was his great object to render his nation prosperous and secure. With this view he made a harbour at Joppa, for the improvement of the trade of the Jews, and he extended the limits of his country. He also renewed the alliance of the Jews with the Romans and the Lacedæmonians; and the whole Jewish nation acknowledged their obligations to him by various tokens of respect, and particularly by recompensing him and his children as perpetual prince and pontiff of their nation. When Demetrius Nicator was taken by the Parthians, Antiochus Sidetes, king of Syria, the brother of Demetrius, applied to him for succour against Tryphon, and not only confirmed the grants of his brother, but allowed him the privilege of coining money, remitted to him all debts owing to the kings of Syria, and declared Jerusalem to be a free and a holy city. Simon sent him men and money to assist him in the reduction of Dora, in which Tryphon had shut himself up. But Antiochus would not receive them, nor would he confirm the articles of his treaty with Simon. He also demanded the surrender of several places, and a thousand talents of silver, threatening, in case of refusal, to enter Judea with troops, and to treat him as an enemy. Simon disregarded his threats; nevertheless he offered a hundred talents for the cities of Joppa and Gazara, of which he had made himself master, because they occasioned great calamities to his country. The army of An-

tiochus, which he had sent to the coasts of the Mediterranean, was defeated by John Hyrcanus, the son of Simon; and three years afterwards Simon visited the cities of Judea, and came to the castle of Docus or Dagon, where his son-in-law Ptolemy, son of Ambubus, resided. But Ptolemy, though he entertained him magnificently, caused him, in the midst of the entertainment, to be massacred, together with his two sons Mattathias and Judas, hoping thus to become master of Jerusalem, and of the whole country. But John Hyrcanus arrived first at Jerusalem. Calmet.

SIMON *the Canaanite*, or *Simon Zelotes*, was an apostle of Jesus Christ. Zelotes, the appellation given to him by St. Luke (vi. 15. Acts, i. 13.) seems to be a translation of the surname Canaanite, given to him by the other evangelists. (Matt. x. 4. Mark, iii. 18.) Some learned persons have supposed, that the term Zelotes denoted his zeal in embracing the gospel of Jesus Christ; but others think, that he was of a sect called Zealots, mentioned by Josephus, (De Bell. l. iv. c. 2. l. vi. c. 1.) It does not appear where he preached, or where he died. Some have asserted that he travelled through Egypt, Cyrenaica, and Africa; that he preached in Mauritania and Libya, and that he propagated the gospel in Britain, closing his life by martyrdom, on the cross, which he endured with incredible courage. Others affirm, that he suffered martyrdom in the city of Sunir, in Persia, on the 28th of October, on which day the Latin church celebrates his festival. The Greeks honour him June 1, and say, that he was Nathanael, the bridegroom at the marriage of Cana.

SIMON *Magus*, or the *Sorcerer*, was a native, as it is said, of the village of Gitton, in the country of Samaria. His history is recited Acts, viii. 5—13. See also Acts, viii. 9, 10, 11. After having been discovered and resisted by the apostles, and particularly by Peter, he is said to have fallen into greater errors and abominations, applying himself more than ever to magic, and taking pride in opposing the apostles, and propagating his errors. It is said by several of the ancient fathers, that at Rome, whither he arrived in the time of the emperor Claudius, about A.D. 41, he was honoured as a deity by the Romans, and by the senate itself, and that a statue was decreed to him in the isle of Tyber, with this inscription: “*Simoni Deo Sancto.*” This fact, however, is disputed by several able critics. It appears, that under the reign of Nero he acquired great reputation by his enchantments; and that he pretended to prove that he was the Christ, and that, as the son of God, he could ascend to heaven; and it has been said, that he really caused himself to be raised in the air, in a fiery chariot, by the assistance of two demons, but that by the prayers of St. Peter he was deserted by his demons, fell down and broke his legs, and afterwards, overcome by grief and shame, threw himself headlong from the top of the house where he lodged. But we shall not multiply these apocryphal stories, which are not worthy of recital. He died, probably, A.D. 65. Simon formed a sect of heretics, who were called *Simonians*; which see.

SIMON, a disciple of Socrates, whose occupation was that of a leather-dresser at Athens, and whose shop was referred to by Socrates and his friends. He is said to have been the first who published the Socratic Dialogues; but none are extant. Simon so much valued freedom of inquiry, that when Pericles invited him to make his house his residence, with the promise of an ample recompence, he refused, alleging, that he would not sell the liberty of speaking his mind at any price.

SIMON, JOHN FRANCIS, an ingenious man of letters, was born at Paris in 1654. He was originally intended for the ecclesiastical profession, and took the degree of doctor

of laws. M. Pelletier de Souzy engaged him as preceptor to his son, and afterwards employed him as his own secretary, and as a remuneration for his services made him counsellor of the fortifications. He became very famous as a writer of inscriptions and legends of medals struck on public occasions, and on this account he was nominated a member of the Academy of Inscriptions and Belles-Lettres. He contributed several learned dissertations to the Memoirs of that body: and he read before it several parts of a medallic history of Lewis XIV. He was an excellent writer both in the Latin and French languages, and in verse as well as prose. In 1712 he was appointed keeper of the royal cabinet of medals. He died in 1719.

SIMON, RICHARD, a biblical critic, was born at Dieppe in 1638. He received his early education in the college of the Fathers of the Oratory in that place, and afterwards entered into that congregation. Quitting it in a very short time, he pursued the study of theology, and of the Oriental languages, in which he made a great proficiency. He entered himself again a member of the Oratory in 1662, when his singular turn of thinking, and unaccommodating temper, involved him in differences, which had nearly caused him to abandon the society for that of the Jesuits. These were, after a time, compromised, and he was sent as professor of philosophy to one of their colleges. The house of the Oratory in Paris possessing a library rich in Oriental writings, Simon was engaged to draw up a catalogue of them, on which occasion he became known to M. de La Moignon, first president of the parliament of Paris. Having performed the task, he returned to his professorship, and there employed himself in literary labours. In the year 1670 he was ordained priest, and in the same year he gave a proof of the liberality of his mind, by undertaking the defence of the Jews at Metz, who had been accused of sacrificing the child of Christian parents. In 1674 he published, under the name Ricared Simeon, "A Treatise on the Ceremonies and Customs at present preserved among the Jews, translated from the Italian of Leo of Modena, with a Supplement respecting the Sects of the Caraites and Samaritans." It was reprinted in 1681, with a supplement, containing "A Comparison between the Ceremonies of the Jews and Discipline of the Church." In 1678 he published "A Critical History of the Old Testament," which, by the boldness of some of its opinions, gave a considerable degree of offence; and though it was protected by the approbation of a doctor of the Sorbonne, and a royal privilege, an order was procured for prohibiting its sale, and the privilege was revoked. In the same year he quitted the Oratory, in order that he might enjoy that freedom which is natural to the mind, and of which he was enthusiastically fond. He was accustomed to express his sense of the advantages of liberty by repeating the words "Alterius ne sit qui suus esse potest." For the purpose of enjoying still more liberty, he resigned his cure four years after this, and spent the remainder of his life in the composition of several works, of which a great part was controversial. He died at Dieppe in 1712, at the age of 74.

Simon was a man of extensive and very deep learning, and an acute critic, but fond of singularity. Few men of letters have engaged in more disputes, and among his adversaries are some of the most eminent men of his time, Catholic as well as Protestant. He has, however, been ever regarded as one of those, who have much contributed to the free and learned discussions which have improved scriptural theology, and though not avowedly a reformer, he was an effective promoter of the Reformation. He published a number of works, and in addition to those already noticed, we may mention "Histoire critique du Texte du Nouveau

Testament;" "Histoire critique des Versions du Nouveau Testament;" "Histoire critique des principaux Commentateurs du Nouveau Testament;" "Nouvelles Observations sur le Texte et les Versions du Nouveau Testament;" "Une Traduction Françoise du Nouveau Testament, avec Remarques Litterales et Critiques," 2 vols. 8vo. This was condemned in the pastoral letters of Noailles, archbishop of Paris, and Bossuet, bishop of Meaux. "Bibliothèque Critique," 4 vols. published under the name of Sainjore, a work suppressed by order of council. "Nouvelle Bibliothèque Choisie," being a sequel to the former. "Lettres Critiques," 4 vols. "Critique de la Bibliothèque des Auteurs Ecclesiastiques de M. Dupin, et des Prolegomenés sur la Bible du même," 4 vols. 8vo. "Histoire Critique de la Croyance et des Coutumes des Nations du Levant." M. Simon left his MSS. and a number of printed books, with marginal notes written with his own hand, to the cathedral library of Rouen.

There was another Simon of some celebrity, a doctor of laws, the author of "A Dictionary of the Bible," explaining the geography of the Old and New Testament, and the ceremonies of the Jews, first printed at Lyons in 1693, and again in 1703, with considerable additions, forming two vols. folio.

SIMON, a great musician among the ancients, who, rejecting former rules of his art, invented a new mode, which was called "Simodia," from his name, in the same manner as the genus invented by Lyfes, was called Lyfodia.

SIMON, M., inventor of pedals for the harp, or *harp à pedale*. See HARP.

SIMON, in *Ichthyology*, a name by which some authors have called the dolphin. It is affirmed, that this fish loves the name, and will come to a person who calls him by it; but this, though recorded by authors of credit, meets with no faith among the judicious readers.

SIMON'S Bay, in *Geography*, a bay on the coast of Africa, 11 miles on the W. side of the Cape of Good Hope: this is the only convenient station for ships to lie in; for although the road without it affords good anchorage, it is too open, and but ill-circumstanced for producing necessaries, the town being small, and supplied with provisions from Cape Town, which is about 24 miles distant. The anchoring place is situated in S. lat. 34° 20', or 34° 23'. E. long. 18° 29'. In April 1780, the dip of the S. end of the magnetic needle was 46° 47', and variation of the compass 22° 16' W. On the full and change days it was high water at 5<sup>h</sup> 55<sup>m</sup> apparent time; the tide rose and fell 5 feet 5 inches; at the neap tides it rose 4 feet 1 inch. Cook's Third Voyage, vol. iii.

SIMONETTA, GIOVANNI, in *Biography*, an historian, was a native of Cassaro, in Sicily. In 1414 he entered into the service of Francesco Sforza, duke of Milan, of which prince his brother Cicco was the confidential minister. After the death of Francesco, he attached himself to his son Galeazzo Maria, to whom he, with his brother, continued so faithful, that when Ludovico Sforza usurped the dukedom, they were arrested and sent prisoners to Pavia. Cicco, in the following year, was beheaded, and Giovanni was banished to Verceci. He, however, returned to Milan, where he was buried about the year 1491. Simonetta composed in Latin a history of the actions of Francesco Sforza from 1423 to 1466, which is accounted one of the best works of that time. It was several times printed. It is also found in Muratori's collection of Italian historians.

SIMONIAL is applied to a person guilty of simony; that is of purchasing a benefice, or other sacred matter, with money. See SIMONY.

SIMONIANS, or SIMONITES, in *Ecclesiastical History*, a sect

a sect of ancient heretics, the first that ever disturbed Christianity; if they might be said to do so, who were little more than mere philosophers, and chiefly made profession of magic.

Simon Magus, so often mentioned in the Acts, was their leader, and died under the emperor Nero; St. Peter still surviving; so that Clemens Alexandrinus is mistaken, when he makes Simon posterior to Marcion.

This impious man, says Mosheim, is not to be ranked among the number of those who corrupted with their errors the purity or simplicity of the Christian doctrine, nor is he to be considered as the parent and chief of the heretical tribe; but he is rather to be placed in the number of those who were enemies to the progress and advancement of Christianity. For it is manifest from all the records we have concerning him, that after his defection from the Christians, in consequence of the severe rebuke which he received from the apostle Peter, he retained not the least attachment to Christ, but opposed himself openly to the divine Saviour, and assumed to himself blasphemously the title of the *supreme power of God*. Orig. adv. Celsum. lib. v. p. 272. ed. Spenceri.

Simon was by birth a Samaritan, or a Jew; when he had studied philosophy at Alexandria, he made a public profession of magic, and persuaded the Samaritans, by fictitious miracles, that he had received from God the power of commanding and restraining those evil beings by which mankind were tormented. As for his doctrines, Mosheim adds, that he was, without doubt, in the class of those philosophers, who not only maintained the eternity of matter, but also the existence of an evil being, who presided, and thus shared the empire of the universe with the supreme and beneficent mind: and he, probably, embraced the opinion of those who held, that matter, moved from eternity by an intrinsic and necessary activity, had by its innate force produced, at a certain period of time, from its own substance, the evil principle which now exercises dominion over it, with his numerous train of attendants. From this pernicious doctrine, the other errors attributed to him concerning fate, the indifference of human actions, the impurity of the human body, the power of magic, and similar extravagancies, flow naturally, as from their true and genuine source.

He rejected the law of Moses, and said he was come to abolish it. He ascribed the Old Testament to the angels, and though he declared himself an enemy to them, he is said to have paid them an idolatrous worship.

This magician farther pretended, that in his person resided the greatest and most powerful of the divine æons; that another æon of the female sex, the mother of all human souls, dwelt in the person of his mistress Helena; and that he came, by the command of God, upon earth, to abolish the empire of those that had formed this material world, and to deliver Helena from their power and dominion. Mosh. Eecl. Hist. vol. i.

This sect is said to have continued to the fourth century. Justin, in his Apolog. 2, says that in his time, *i. e.* about A.D. 150, almost all the Samaritans, and some few others elsewhere, acknowledged Simon as the greatest of the gods. Clemens Alexandrinus (Shan. l. ii.) says that his followers worshipped him. About the year 249 this sect was reduced to about thirty persons, according to Origen (Cant. Celsum, l. i.); and elsewhere (l. v.), he says that they were quite extinct. But it appears from other testimonies, that some of them remained even at the beginning of the fifth century. Eusebius (Hist. Eecl. l. ii. c. 1.) speaks of Simonians, that mingled themselves among the Catholics, and received Catholic baptism; but who afterward spread in secret the venom of their doctrine. Several were discovered and ex-

elled the church about the beginning of the fourth century. See GNOSTICS.

SIMONIDES, in *Biography*, a celebrated Grecian poet, born in the isle of Chios, was the son of Leocrates, and flourished in the fifth century before the Christian era. He excelled in various kinds of poetry, but especially in the elegiac, for which, as we learn from Horace and Quintilian, he was almost proverbially famous in antiquity. One of his most famous compositions was entitled "The Lamentations," of which the following fragment is all that remains, but this justifies his title to great excellence as a writer.

"Sweet child! what anguish does thy mother know,  
Ere cruel grief has taught thy tears to flow!  
Amidst the roaring wind's tremendous sound,  
Which threats destruction, as it howls around,  
In balmy sleep thou liest, as at the breast,  
Without one bitter thought to break thy rest.  
While in pale, glimmering, interrupted light  
The moon but shews the horrors of the night.  
Didst thou but know, sweet innocent! our woes,  
Not opiate's pow'r thy eye-lids now could close.  
Sleep on, sweet babe! ye waves in silence roll,  
And lull, O lull to rest! my tortur'd soul."

Simonides was endowed with a most extraordinary memory, and some have attributed to him the invention of the art of recollecting by localizing ideas, which has lately been brought into fashion in this country. The introduction of some of the compound letters of the Greek alphabet is also ascribed to him. He lived to an advanced age, and at the age of eighty gained a prize for poetry. According to Pliny, Simonides added the eighth string to the lyre. In his old age, perhaps from seeing the respect which money procured to such as had lost the charms of youth, and power of attaching mankind by other means, he became somewhat mercenary and avaricious. He was frequently employed by the victors at the games to write panegyrics and odes in their praise, before his pupil Pindar had exercised his talents in their behalf; but Simonides would never gratify their vanity in this particular, till he had first tied them down to a stipulated sum for his trouble; and, upon being upbraided for his meanness, he said, that he had two coffers, in one of which he had, for many years, put his pecuniary rewards; the other was for honours, verbal thanks, and promises; that the first was pretty well filled, but the last remained always empty. And he made no scruple to confess, in his old age, that of all the enjoyments of life, the love of money was the only one of which time had not deprived him. It is mentioned as a subject of dispraise, that Simonides was one of the first who wrote verses for money, and that he travelled through the cities of Asia, selling eulogies on the victors in the public games. He paid a visit, in advanced life, to Hiero, king of Syracuse, to whom he gave the celebrated answer respecting the nature of God that has been handed down from generation to generation to the present time in the writings of Cicero. Hiero having asked his opinion on the subject, he requested a day to consider of it; when this was expired, he doubled the time, and thus he did repeatedly, till the monarch desired to know his reason for this proceeding: "It is," said he, "because the longer I reflect on the question, the more difficult it appears to be." He was reported to be extremely avaricious; he was, however, justly ranked among the philosophers and poets, and though sensible of the value of money, he knew what was more valuable. Undergoing shipwreck on a voyage, while the other passengers encumbered themselves with their most valuable effects, he left his behind him, saying, "I carry with me all that is mine;" and when he arrived safe at Clazomene,

zomene, his fellow sufferers being either drowned or pillaged, he met with a citizen acquainted with his poetry, who liberally supplied all his wants. It was a witty reply which this author made to Hiero's queen, who demanded of him whether knowledge or wealth was most to be preferred: "Wealth," said he; "for I see every day learned men at the doors of the rich." When he was accused of being so fordid, as to sell part of the provisions with which his table was furnished by Hiero, he said he had done it, in order "to display to the world the magnificence of that prince, and his own frugality." In justification of his passion for wealth, he said, "I choose rather to be useful to my enemies after I am dead, than burdensome to my friends while I am living." He is said to have been sufficiently eloquent to reconcile two princes extremely irritated against each other, and actually at war. He was unquestionably one of the most conspicuous characters of his time. Of his numerous works only a few fragments remain, which are published in the *Corpus Poetarum Græcarum*.

**SIMONOR**, in *Geography*, a small island in the Sooloo Archipelago. N. lat. 4° 59'. E. long. 119° 50'.

**SIMONOSAKI**. See **XIMONOSEQUI**.

**SIMONTORNYA**, or **SIMON THURN**, a town of Hungary, situated on the Sarand, with a strong castle, taken by the Imperialists in the year 1686; 32 miles S.S.W. of Buda. N. lat. 46° 50'. E. long. 18° 25'.

**SIMONY**, **SIMONIA**, the crime of trafficking with sacred things; particularly the corrupt presentation of any one to an ecclesiastical benefice for money, gift, or reward.

The word is borrowed from Simon Magus, who is mentioned in the Acts of the Apostles, as offering to buy the power of working miracles with money: though the purchasing of holy orders seems to approach nearer to his offence.

By the English canons, anno 1229, simony is not only committed by an agreement for money in hand, or to be paid yearly; but by any other profit or emolument; any reward, gift, or benefit, directly or indirectly; or by reason of any promise, grant, bond, &c. and this either in the acceptance of a living, or in an exchange or resignation.

Simony was by the canon law a very grievous crime; and it is so much the more odious, because, as Sir Edward Coke observes, it is ever accompanied with perjury; for the presentee is sworn to have committed no simony. However, it was not an offence punishable in a criminal way at the common law; it being thought sufficient to leave the clerk to ecclesiastical censures: but many acts of parliament have been made to restrain it by means of civil forfeitures. Thus the statute of 31 Eliz. c. 6. enacts, that if any patron, for money, or any other corrupt consideration or promise, directly or indirectly given, shall present, admit, institute, induct, install, or collate any person to an ecclesiastical benefice or dignity, such presentation shall be void, and the presentee be rendered incapable of ever enjoying the same benefice, and the crown shall present to it for that turn only: moreover, both the giver and taker shall forfeit two years' value of the benefice or dignity; one moiety to the king, and the other to any one who will sue for the same. If persons also corruptly resign or exchange their benefices, both the giver and taker shall, in like manner, forfeit double the value of the money, or other corrupt consideration.

Farther, by the statute 12 Ann. stat. 2. c. 12, if any person, for money or profit, shall procure, in his own name, or the name of any other, the next presentation to any living ecclesiastical, and shall be presented thereupon, this is declared to be a simoniacal contract, and the party is subjected to all the ecclesiastical penalties of simony, is

disabled from holding the benefice, and the presentation devolves to the crown.

In the construction of these statutes, these points, says judge Blackstone, seem to be clearly settled.

1. That to purchase a presentation, the living being actually vacant, is open and notorious simony.

2. That for a clerk to bargain for the next presentation, the incumbent being sick and about to die, was simony, even before the statute of queen Anne; and now, by that statute, to purchase, either in his own name or another's, the next presentation, and be thereupon presented at any future time to the living, is direct and palpable simony.

But, 3. It is held, that for a father to purchase such a presentation, in order to provide for his son, is not simony; the son not being concerned in the bargain, and the father being by nature bound to make a provision for him.

4. That if a simoniacal contract be made with the patron, the clerk not being privy thereto, the presentation for that turn shall indeed devolve to the crown, as a punishment of the guilty patron; but the clerk who is innocent, does not incur any disability or forfeiture.

5. That bonds given to pay money to charitable uses, on receiving a presentation to a living, are not simoniacal, provided the patron or his relations be not benefited thereby; for this is no corrupt consideration, moving to the patron.

6. That bonds of resignation in case of non-residence, or taking any other living, are not simoniacal, there being no corrupt consideration therein, but such as is only for the good of the public. So also bonds to resign, when the patron's son comes to canonical age, are legal; upon the reason before given, that the father is bound to provide for his son.

7. Lastly, general bonds to resign at the patron's request, are held to be legal; for they may possibly be given for one of the legal considerations before-mentioned, and where there is a possibility that the transaction may be fair, the law will not suppose it iniquitous without proof; but if the party can prove the contract to have been a corrupt one; such proof will be admitted, in order to shew the bond simoniacal, and therefore void. Neither will the patron be suffered to make an ill use of such a general bond of resignation; as by extorting a composition for tithes, procuring an annuity for his relations, or by demanding a resignation wantonly, and without good cause, such as is approved by the law, as for the benefit of his own son, or on account of non-residence, plurality of livings, or gross immorality in the incumbent. Blackst. Comm. b. ii.

**SIMONY** is also committed by buying or selling the sacrament, baptism, ordination, or absolution; as well as by the nomination and collation to a benefice, a place in monastery, or the like.

By 31 Eliz. cap. 6, persons who shall corruptly ordain or license any minister, or procure him to be ordained or licensed, shall incur a forfeiture of 40*l.*, and the minister himself of 10*l.*, besides an incapacity to hold any ecclesiastical preferment for seven years afterwards. See **PRESENTATION**.

Some have pretended it to be sufficient to avoid the charge of simony, if only the ordination were gratuitous, though the revenues were bought and sold as a temporal thing. But the canons of several councils have condemned this subtle distinction; since the revenues are attached to an ecclesiastical office purely spiritual.

Casuists distinguish three kinds of simony; *viz.*

**SIMONY, Mental**, is that which is restricted to the mere will and inclination, without ever breaking forth into act. As when a present is made to a collator, without taking any notice, that we expect a benefice from him. This kind of simony is only punishable in *foro conscientie*.

**SIMONY,**

**SIMONY, Conventional**, is where there is an express act, and a formal bargain, though it never come to an execution.

**SIMONY, Real**, is where the convention is executed on both sides; which last is the most criminal of all. The canonical penalty of simony is deposition in a clerk, and excommunication in a layman.

It is a maxim among the Romish canonists, that there is no simony in the court of Rome; because the pope acts there as an absolute sovereign; they also say, that resignations *in favorem* are not to be admitted but by the pope, as favouring a little of simony. On these occasions, however, the parties always swear, that there had been no deceit, collusion, simony, or other illegal covenant.

Peter Damian distinguishes three kinds of simony: that of money, that of the tongue, and that of services.

**SIMONY of Money**, or *Per munus a manu*, is where money is really paid down for a benefice: he adds, that the same is likewise committed, by expending money to live at court to obtain a benefice.

**SIMONY of the Tongue**, or *Per munus a lingua*, consists in flattering the collator, or making one's self agreeable by complaisance and commendation.

**SIMONY of Services**, or *Per munus ab obsequio*, consists in doing for them good offices to obtain a benefice.

It was agreed by all the justices, Trin. oct. Jac. primi, that if the patron presented any person to a benefice with cure, for money; such presentation, &c. is void, though the presentee were not privy to it; and the statute gives the presentation to the king; but this is now repealed.

**SIMORI**, in *Geography*, a town of Naples, in Calabria Ultra; 13 miles N.E. of Squillace.

**SIMORRE**, a town of France, in the department of the Gers; 13 miles S.E. of Auch.

**SIMPLA NOBLA**, in *Botany*. See **PHYLLIS**.

**SIMPLARY**, **SIMPLARIS**, in *Antiquity*, a Roman soldier, who had only single pay. Thus called, in opposition to the *duplares*, or such as had double pay.

**SIMPLE**, **SIMPLEX**, something not mixed, or compounded; in which sense it stands opposed to *compound*.

**SIMPLE Bodies or Elements**, in *Chemistry*, are those substances which have not yet been decomposed.

In every era of chemical science, something like a system or theory has prevailed, which has had for its basis a certain number of bodies, called elements or simple bodies, of which all other bodies were formed. This has ever had the good effect of stimulating the minds of enquirers, and has tended much to the progress of this useful branch of philosophy. Theory has succeeded theory, varying widely from, and in some instances contradicting each other, till philosophers have become very cautious in the admission of the elementary nature of bodies; and hence have agreed in the above general definition of a simple body.

The limited proportions in which bodies combine, is sufficient to convince us, that simple bodies consist of hard unchangeable particles or atoms, which are not practically divisible. And the general forms of the crystals of compound matter go far to shew, that these atoms are spheres, a form the best calculated for motion, and under which they would be the least likely to change. How many varieties of these unchangeable spherical particles there exist, it is difficult to say; and what ratio they bear to each other, in density or magnitude, we are equally at a loss to determine. One great step, however, has been made, which may lead us to more important conclusions. Although we are ignorant of the absolute dimensions and densities of these atoms, we are now in a way to acquire a knowledge of their relative weights, by which we shall be enabled to calculate the proportions of compound bodies, by simply knowing of what

elements they are composed. The use of experiment will be to find out the elements of a compound, and rudely guess at its proportions; but the exact proportion will require to be determined by calculations, which will render chemistry as complete as astronomy.

There is the greatest reason to believe, that the atoms of simple matter attract each other by the same laws with gravitation. Sir Isaac Newton supposes, that in gold, which in his time was considered the densest body, the pores or interstices between its particles greatly exceed its material part. Of what density, therefore, must we consider the atoms of bodies. Our present idea of density is very vague, and varies with the temperature, and depends, therefore, upon the quantity of caloric they contain. If these atoms were to be finally deserted by the caloric, they would come in contact; and if they were spheres, the resulting specific gravity would be  $\frac{4}{3}$  of the specific gravity of the atoms themselves. The caloric, on the contrary, if deserted by the atoms, would, from its repellent property, be dispersed to an unlimited extent. When, however, these two species of matter combine, they still retain their original properties; but the attraction of the atoms decreases, as they recede, by new additions of caloric in a less ratio than the repulsion of the caloric, and the two powers are kept in equilibrium by change of distance between them. If the attraction be as the square of the distance, and the repulsion as the cube; then, if the distances be successive intervals of 1, 2, 3, &c. the attractions at these points will be 1,  $\frac{1}{4}$ ,  $\frac{1}{9}$ , &c. and the repulsion 1,  $\frac{1}{8}$ ,  $\frac{1}{27}$ , &c. Therefore, the caloric at each point, to make the atoms stand in equilibrium at these respective distances, will be 1, 2, 3, &c. for  $1 \times 1 = 1$ ,  $\frac{1}{4} \times 2 = \frac{1}{2}$ ,  $\frac{1}{9} \times 3 = \frac{1}{3}$ , and so on. It is under this form that the specific gravity of a body is taken; but we know not what that it must be very considerable. In proportion as this is the case, we are to expect a greater attractive force agreeably to the laws of gravitation. If the earth were to be condensed to half its diameter, the weight of bodies on its surface would be quadrupled. This circumstance, aided by the proximity of the atoms in chemical combination, and the state of aggregation, in which solids exist, will make us cease to wonder at the powers of chemical attraction, and at the same time gives a lively hope, that the same attraction is common both to gravity and chemical combination. However indeterminate this problem may appear, we understand that some experiments are soon to be instituted for settling this point.

The experiments will in the first place determine, whether these attractions are the same, or not: if they are the same, the experiments will determine, and point out the numbers which will express the strength of affinity between different bodies; the only facts which are now wanting to make chemistry a complete science.

In the present state of chemical science, those bodies considered as elements are divided into two classes; the one called combustible or inflammable, and the other supporters of combustion; because in combining with the first class, much light and heat are developed.

The first class, which is by far the most numerous, consists chiefly of metals, with only a few exceptions. These are exhibited in the following table, which also contains the weights of their atoms and specific gravities; hydrogen, the lightest atom, being 1.

If the views of Gay Lussac, the French chemist, be correct, in a memoir on Jodine, or Iodine, which has been published in Dr. Thomson's Annals, we shall be hardly warranted in drawing this line between the combustible bodies, and those

## SIMPLE BODIES.

which support combustion. Some of the latter appear to act the part of both. This is evidently the case with sulphur, which gives light and heat to a certain extent in its combination with some of the metals, and also when it combines with oxygen, with which, as an inflammable body, it forms an acid. In the opposite characters, like chlorine and iodine, it forms an acid with hydrogen, which is now termed the hydrofulphuric acid. Gay Lussac goes farther, and supposes that phosphorus, carbon, and azote, have a similar double property. Carbon he supposes to be the acidifying principle of some of the vegetable acids, and that azote acts a similar part in the prussic acid.

### Simple Combustible Bodies.

Iodine	-	117
Fluorine	—	—

The bodies of the first class, with the exception of sulphur, phosphorus, azote, hydrogen, and carbon, are known to be metals; and there is strong reason to believe that hydrogen is a metal in the elastic form. It is very remarkable, that those bodies, the metallic nature of which is doubtful, appear to possess the property of combining more strongly with inflammable bodies, than the metals with each other in forming alloys. Indeed, the combinations of most of the metals with those that are not metallic, are generally conspicuous, and always definite.

The first of the second class of bodies, viz. oxygen, has long been considered a simple body. The second has been lately, by the French chemists and by Sir Humphrey Davy, considered in the same light. It was till lately considered as a compound of muriatic acid and oxygen, from which it was called oxymuriatic acid. Its name is now changed to chlorine, from its green colour. Iodine is another substance of the same class, exhibiting striking properties with inflammable bodies. Its name has been derived from the violet colour of its vapour. It was discovered in kelp, a substance which consists of soda combined with certain impurities. The iodine is extracted from it by the following process. Infuse the kelp in hot water till all the soluble part is taken up; then evaporate the solution till the carbonate of soda crystallizes on cooling. In this way, by repeating the evaporation and cooling, separate as much as possible of this salt; then continue the evaporation to dryness. This residuum is now to be introduced into a glass retort, or a long-necked matrass, and a quantity of sulphuric acid poured upon it. This is then applied to, at first, a gentle heat. When the temperature reaches about 300°, a purple or violet-coloured vapour appears in the neck of the retort, which condenses into shining opaque crystals of the appearance of plumbago. These crystals are pure iodine. Iodine, in the solid form, is of a greyish-black colour, its vapour being of a beautiful violet. Its crystals have a shining scaly appearance, like mica. Their form is that of rhomboidal plates, and sometimes of elongated octohedrons. It is soft and friable, so as to rub to powder between the fingers. It stains the skin of a deep brown colour, but not permanently. It has the smell of chlorine or oxymuriatic gas. Its taste is acid, although it requires seven thousand parts of water for its solution. It destroys vegetable colours, like chlorine, but with less energy.

Its specific character is 4.948 at the common temperature, water being 1. It fuses at 225° of Fahrenheit, and assumes the elastic form at 374° or 356°; but it will come over in distillation with the vapour of water. It is a non-conductor of electricity.

Iodine, like oxygen and chlorine, has the property of supporting combustion with combustible bodies. With some of these it forms compounds analogous to oxids, and with hydrogen it forms an acid resembling the muriatic acid, the compound formed by hydrogen with chlorine. In these instances, iodine and chlorine have not only the property of supporters of combustion, but of forming acids with an inflammable base. They, however, in their turns, act the part of combustible bodies, by forming acids with oxygen. It appears also, from the views of Gay Lussac, that sulphur has also this double property, for by combining with hydrogen it forms the well-known compound called sulphuretted hydrogen, which possesses the properties of an acid, and is rendered so by acting the part of oxygen with the inflammable base. On the contrary, it forms sulphuric acid with oxygen by itself, acting the part of an inflammable base.

It also appears to this philosopher, that azote, carbon, and phosphorus, may have the power of producing acidity by

## SIMPLE BODIES.

by their combining with certain inflammable bases. He is of opinion, that most of the vegetable acids do not owe their acidity to oxygen combined with hydrogen and carbon, but to the carbon acting the part of oxygen with hydrogen, as sulphur, chlorine, and iodine do with the same.

Agreeably to this view, we shall give some of the facts attendant on chlorine, iodine, and sulphur, in their combinations with hydrogen and oxygen.

To the binary combinations of these bodies with others, in which they have no acidity, Gay Lussac has given the names of chlorurets, iodurets, and sulphurets; as chloruret of potassium, ioduret of zinc, sulphuret of iron, and so on. When they form acids with hydrogen, they are termed hydrochloric, hydraodic, and hydrosulphuric acids. The acids formed by their combinations with oxygen he terms chloric, jodic, and sulphuric acids. The chloric acid is the same with what has been called the hyperoxymuriatic acid, and forms with potash what has been termed hyperoxymuriate of potash. The jodic acid forms a compound with potash, having similar properties, and affording a large quantity of dissoluble oxygen.

The hydrochlorates are the salts which have been called muriates, and have some resemblance to the hydriodates, a set of salts formed by the acid arising from the union of iodine with hydrogen, and the different saline bases.

The hydraodic acid is formed by first combining phosphorus with iodine, in the proportion of one of the former to nine of the latter. This compound being brought in contact with water, affords the hydraodic acid. The water is decomposed, the oxygen of which combines with the phosphorus to form phosphoric acid, and the hydrogen with the iodine, forming the hydraodic acid. If the iodine and phosphorus were 18 of iodine to 1 of phosphorus, then phosphoric acid would be formed in the water. On the other hand, if the iodine were 4.5 to 1 of phosphorus, then hydraodic acid would be formed, and a compound of phosphorus and oxygen, consisting of two atoms of the former to one of the latter. This is the red insoluble substance which has been called oxyd of phosphorus.

In all these processes the hydraodic acid is evolved in fumes smelling like muriatic acid, and may be collected, like it, in the gaseous form. This gas is about 60 times heavier than hydrogen. Water absorbs a large quantity of it, so as to form a very strong acid, of the specific gravity of 1.7. This acid is decomposed in two ways, principally by such bodies as easily separate its hydrogen and set free the iodine, such as the sulphuric and nitric acids, and many of the oxyds, by which water and iodurets are formed. It is also decomposed by the superior attraction of iodine for other bodies, setting the hydrogen free. Such is the case with most of the metals.

The compounds of the hydraodic acid with different saline bases form salts, resembling the hydrochlorates (muriates) and the hydrosulphates. The other binary compounds of iodine, and the different combuible bodies which are called iodurets, are very conspicuous. Most of these are insoluble in water. Those metals which decompose water, form soluble iodurets; as in these instances the ioduret becomes an hydriodate.

Another set of compounds results from iodine, which we have already called iodates. Iodine combines with oxygen, in the proportion of 5 atoms of the latter to 1 of the former, which is 117 iodine to  $5 \times 7.5 = 37.5$  of oxygen. This constitutes the jodic acid.

This acid cannot be directly formed by combining iodine with oxygen; but it is formed during the action of iodine

upon potash, soda, barytes, strontian, lime, and magnesia, when water is present. The changes are precisely what take place, when chlorine is substituted for iodine. Two salts are formed with the base employed; the one with chloric or jodic acid, and the other with hydrochloric or hydraodic acid.

When iodine in vapour is passed through a solution of potash, four atoms of iodine decompose four atoms of water, by which four atoms of hydraodic acid are produced. These unite with four atoms of potash, forming as many compound atoms of hydriodate of potash. The four atoms of oxygen, separated from the water, now unite with a fifth atom of iodine, and a fifth atom of potash; the whole of which will amount to an atom of ioduret of potassium, united to five atoms of oxygen, constituting an atom of iodate of potash. It will appear, therefore, that during the formation of any of the iodates or the chlorates, that for every atom of such iodate or chlorate there will be formed, at the same time, four atoms of an hydriodate or hydrochlorate.

In the example above stated, an atom of iodate of potash will be 1 atom of iodine (117) + 1 atom of potassium (37.5) + 5 atoms of oxygen ( $5 \times 7.5 = 192$ ). The 4 atoms of hydriodate of potash will consist of 4 atoms of hydraodic acid ( $4 \times (117 + 1)$ ) + 4 atoms of potash ( $4 \times (37.5 + 7.5)$ ) =  $472 + 180 = 652$ . The ratio, therefore, of the iodate of potash to the hydriodate, will be 192 to 652, or 100 to 340 nearly. In the crystalline form, however, the hydriodate of potash does not crull, but is converted into ioduret of potassium, which will consist of an atom of iodine (117) added to an atom of potassium (37.5) = 154.5, and  $154.5 \times 4 = 618$ , the quantity of the crystallized ioduret to the iodate, which will be 100 of the latter to 322 of the former nearly.

It is rather out of place to enter into the particulars of bodies; but this last substance, from its recent discovery, has not been before mentioned in this work. There are also many interesting particulars respecting chlorine; but these are rather new explanations, under the idea of this being a simple body, than new facts.

We know little more of the body called fluorine, than that it is in all probability a body combining with hydrogen to form fluoric acid, in the manner that chlorine and iodine form hydrochloric and hydraodic acids with that body. To the combinations of chlorine with the different bodies, in which no acidity prevails, Dr. Thomson has proposed the name of chlorids, as being more agreeable to the termination in the word oxyds; and we suppose would adopt, for similar combinations of iodine, iodids; and we should expect, from the sulphurates being analogous, that they would be called sulphids, to keep up the same uniformity. The French chemists (see Gay Lussac's Memoir on Iodine, Thomson's Annals, vol. v.) have adopted for the same compounds the termination already used for the sulphurets, *viz.* chlorurets, iodurets; and for the combinations of carbon and azote with the same bodies, they would use *carburets, azoturets*, or, what is better, *nitrogurets*. We see no objection to this termination for all the binary compounds not possessing acidity, as in fact there would be no other change than that of altering oxyd into *oxuret*. The acids would still retain their terminations, *ous* and *ic*, distinguishing those which do not contain oxygen by the acidifying substance. The salts, as at present, would derive their names from the acids. See NOMENCLATURE.

SIMPLE, in Botany, is a general name given to all herbs and plants; as having each its particular virtue, by which it becomes a simple remedy.

The simples from the Levant, and the East Indies, were not known among us till about the year 1200.

**SIMPLE Leaves.** See LEAF.

The term *simple* is also technically applied to some other parts of a plant. A *simple calyx* is used in the *columniferous* order, in opposition to the double one of *Malva*, *Hibiscus*, and many other genera of that order. A *simple stigma* means, that the part in question is of no elaborate or peculiar shape, or structure, but merely adequate to perform its requisite functions. This end is sufficiently answered by a rather obtuse, though not dilated, figure, just enough to receive the pollen upon a moist surface, or point. If a stigma be acute, or taper-pointed, that character should be specified; as also if it be capitate, concave, lobed, fringed, &c.; in all which latter cases it is no longer *simple*. See STIGMA, and FECUNDATION of Plants.

A *simple stem*, or *stalk*, is destitute of branches, or subdivisions. Such also is *simple pubescence*, the hairs of which are unbranched and straight; not stellated, entangled, or hooked.

**SIMPLE**, in French *Music*, in an air with variations, implies the air itself, in opposition to the *doubles* or variations. See AIR, and DOUBLE.

**SIMPLE Cadence**, is that where the notes are all equal through all the parts.

**SIMPLE Concorde**, are those in which we hear at least two notes in consonance; as a third and a fifth; and, of consequence, at least three parts. This is either done immediately, and is called the *harmonical triad*, or in a more remote manner, that is, when the sounds, that are not bass, are one or two octaves higher. This distance has no ill effect in the third, but in the fifth it has; and, generally speaking, the nearer, or more immediate, the concords are, the better. See CONCORD.

They also say **C simple**, or plain, in opposition to **C accented**.

**SIMPLE Counterpoint**, *Fugue*, *Interval*, *Sounds*, and *Triple*. See the substantives.

**SIMPLE Equation**, *Fraction*, and *Surd*, in *Algebra*. See the substantives.

**SIMPLE Quantities**, are those which consist of one term only; as  $+a$ ,  $-ab$ , or  $+abc$ ; accordingly they are opposed to compound quantities.

**SIMPLE Glands**, in *Anatomy*. See GLANDS.

**SIMPLE Anomaly** and *Excentricity*, in *Astronomy*. See the substantives.

**SIMPLE Form**, *Modes*, *Necessity*, *Opposition*, and *Proposition*, in *Logic* and *Metaphysics*. See the substantives.

**SIMPLE Average**, *Benefice*, *Church*, *Deposit*, *Estate*, *Fee*, *Force*, *Larceny*, *Resignation*, and *Vassalage*. See the substantives.

**SIMPLE Contract**, *Debts by*, are such, where the contract upon which the obligation arises is neither ascertained by matter of record, nor yet by deed or special instrument, but by mere oral evidence, or by notes unsealed, which are capable of a more easy proof, and (therefore only) better than a verbal promise.

**SIMPLE Diachylon**, *Diacodium*, *Diamorum*, *Diaprunum*, *Drolix*, *Fomentations*, *Hydromel*, *Mixture*, *Oxymel*, and *Waters*. See the substantives.

**SIMPLE Fencing**. See FENCING.

**SIMPLE Flank** and *Tenaille*, in *Fortification*. See the substantives.

In *Geometry*, we say, the most simple demonstrations are the best.

In *Grammar*, we have simple words, or primitives; and compounds, which have some particle added to them.

In *Jurisprudence*, they say a simple donation, in opposition to a mutual or reciprocal one: a simple sale, in opposition to that made with a reservation of the faculty of redemption; and simple homage, in opposition to liege homage.

**SIMPLE Fossils**, in *Natural History*. See FOSSILS.

**SIMPLE Machine**, *Motion*, *Pendulum*, and *Wheel*, in *Mechanics*. See the substantives.

The simplest machines are always the most esteemed.

**SIMPLE Vision**, in *Optics*. See VISION.

In *Pharmacy*, there are simple remedies, and compounds; the former of which are usually preferable to the latter.

**SIMPLE Taste**, in *Physiology*. See TASTE.

**SIMPLE History** and *Style*, in *Rhetoric*. See the substantives.

**SIMPLE Fracture** and *Ulcer*, in *Surgery*. See the substantives.

**SIMPLER'S JOY**, in *Botany*. See VERBENA.

**SIMPLEX OCLUSUS**, in *Surgery*, the name of a bandage for the eye.

**SIMPLICITY**, in *Ethics*. See SINCERITY.

**SIMPLICITY**, in *Music*. There is much cant about simplicity in music, among the exclusive admirers of old things, and lamentation for the loss of our old melodies to the songs of Chaucer, Gower, Lydgate, and others, of which the words are still extant. But if we may judge by what has escaped the ravages of time, of a later date, the loss of our musical compositions of this period may be supported without much affliction. We may perhaps heighten that affliction considerably by censuring modern refinements, and extolling the charms of ancient simplicity; but simplicity in melody, beyond a certain limit, is unworthy of the name that is bestowed upon it, and encroaches so much upon the rude and savage boundaries of uncouthness and rusticity, as to be wholly separated from proportion and grace, which should alone characterize what is truly simple in all the arts; for though they may be ennobled by the concealment of labour and pedantry, they are always degraded by an alliance with coarse and barbarous nature.

Old melodies, when we find them, and can ascertain their dates, are curious historical facts in the annals of the musical art; and afford us more satisfactory information concerning our ancient national taste, than all the verbal descriptions in prose and verse can do. And it must be owned, that though the natives of Scotland, Ireland, and Wales, can boast of national tunes, both plaintive and spirited, that are characteristic, pleasing, and distinct from each other, the English have not a melody which they can call their own, except the hornpipe and Cheshire-round. The hornpipe, indeed, was in all probability British, or Welsh; as the pip-corn, or pipe of Cornwall, was an *armoric* instrument and tune, brought thither by the Britons, driven to that part of the island, and into Brittany and Wales, by the Saxons. The Cheshire-round is a melody of the same kind. See HORNPIPE, and plate of *National Tunes*.

**SIMPLICIUS**, *Pope*, in *Biography*, a native of Tivoli, was elected to the pontificate in September 467, on the death of Hilary. During the time of his possessing the see of Rome, great commotions existed in the eastern and western empire. The latter terminated in the person of Augustulus, who was dethroned by Odoacer, king of the Heruli, an Arian. In the East the emperor Zeno was dethroned by Basiliscus, who declared against the council of Chalcedon. Simplicius does not appear to have been personally molested in these changes, but he was frequently called upon to exert himself in defence of the claims of his see, and of the orthodox faith. He moreover extended and strengthened

strengthened the papal jurisdiction over the western church, by appointing the bishop of Seville apostolic vicar in the province of Bœtica, and by an attack upon the metropolitan rights of the bishop of Ravenna, together with other vigorous measures. Simplicius died in the year 483, after having filled the papal chair nearly fifteen years and a half. There are extant eighteen of his letters, chiefly relating to matters of discipline, and the affairs of the eastern churches.

**SIMPLICIUS**, a Greek philosopher of the sixth century, was a native of Cilicia. He was a disciple of Ammonius the Peripatetic, and Damascius the Stoic; but in his own mode of philosophizing, he endeavoured to unite the Platonic and Stoical doctrines with those established by Aristotle. Of this combination of heterogeneous tenets, his "Commentary upon the Enchiridion of Epictetus" is said to be a good example. Of this work, Fabricius affirms there is nothing in pagan antiquity better calculated to form the morals, or afford juster views of divine providence. Simplicius wrote commentaries upon Aristotle. He was one of the philosophers who took refuge with Chosroes, king of Persia, from an apprehended persecution by Justinian; but they returned to Athens, upon a truce between the Romans and Persians in 549, having stipulated for a toleration. His commentaries upon Aristotle have been several times published in Greek. Those on Epictetus were published in Greek and Latin, with the notes of Wolfius and Salmasius. They have been translated into the English and French languages.

**SIMPLIFYING**, in *Ecclesiastical Matters*, is the taking away of a cure of souls from a benefice, and dispensing the beneficiary from residence.

Several benefices, which have been simplified, now require residence; and many others, which required residence, have been simplified.

Some use the word in a more extensive signification, *viz.* for the shortening a relation, &c. or retrenching every thing not precisely necessary. When the matter of fact shall be simplified, and stripped of its vain circumstances, the court will see, &c.

**SIMPLOCE**, in *Rhetoric*, a figure which comprehends both the anaphora and epitrophe. In this figure the several members begin and end with the same word. Thus St. Paul: *Are they Hebrews? So am I. Are they Israelites? So am I. Are they the seed of Abraham? So am I.* 2 Cor. xi. 22.

**SIMPLON**, in *Geography*, a mountain of Switzerland, over which is a passage from the Valais to the duchy of Milan; 6597 feet above the level of the sea; 31 miles E. of Sion.

**SIMPLUDIARIA**, in *Antiquity*, a kind of funeral honours paid to the deceased at their obsequies.

The word is formed from the Latin *simplex*, and *lulus*; whence *simpludiaris*, or *simpludaria*, q. d. *simple games*. Some will have *simpludaria* to be the funerals at which games were exhibited: such is the sentiment of Paulus Diaconus. Festus says, they were those, in the games of which nothing was seen but dancers and leapers, called *convitatores*; who, according to M. Dacier, were persons who run along the malls and yards of vessels or boats, called *corbes*.

In other respects, those two authors agree as to the kind of funerals called *simpludaria*; *viz.* that they were opposite to those called *indiciosa*; in which, besides the dancers and leapers observed in the *simpludaria*, there were defultores, or people who vaulted on horses; or perhaps horse-races, in which the cavaliers leaped from horse to horse at full speed.

**SIMPSON**, THOMAS, in *Biography*, a celebrated self-taught mathematician, was born at Market Bosworth, in Leicestershire, in 1710. His father, who was a weaver in that town, intended to bring him up to his own trade, and took little heed of his education. Nature, however, had endowed him with fine talents, and an ardour of disposition, which excited him to nobler pursuits. At an early period he gave indications of his turn for study, by eagerly perusing every book that fell in his way, and omitting no opportunity to acquire instructions from others. His father, finding that he was thus led to neglect his work, endeavoured to restrain him from what he regarded as idle pursuits; but after some fruitless attempts, a difference was produced between them, which at length terminated in an open rupture, and Thomas left his father's house, and married the widow of a taylor, with whom he resided at Nuneaton, where he continued some time working at his trade, and improving his knowledge. Here he became acquainted with a travelling pedlar, who lodged in the same house, and who, to the profession of an itinerant merchant, had united the more profitable one of a fortune-teller. An intimacy was formed between them, and as the pedlar was going to Bristol, he lent, during his absence, Cocker's Arithmetic to Simpson, to which was subjoined a short appendix on Algebra; and a book on Genitures, by Partridge, the almanac-maker. These books he studied so closely, that on the pedlar's return, he was astonished to find that Simpson was little inferior to himself in the art of calculating nativities; and he predicted that he would shortly be his superior. Encouraged by this prophecy, he at first determined to embark in the trade of a fortune-teller; and by this occupation, and teaching a school, he found means to support himself without weaving, which he now entirely abandoned, and was soon regarded as the oracle of the neighbourhood. From this time he seems to have lived very comfortably, till an unfortunate event involved him in a deal of trouble. Having undertaken to raise the devil, in order to answer certain questions to a young woman, who consulted him respecting her sweetheart, then absent at sea, the credulous girl was so frightened on the appearance of a man from beneath some straw, who represented the devil, that she fell into violent fits, from which she was with difficulty recovered, and which for a considerable time threatened insanity or fatuity. In consequence of this exertion of his art, he was obliged to leave the place, and he removed to Derby, where he remained a few years, working at his trade by day, and instructing pupils in the evening. He became a writer in the Lady's Diary in the year 1736: his first questions were stated in verse, and are of that kind as shew that at this period he had made some progress in mathematical knowledge. He from this period applied himself with great ardour to every branch of the analytic science, and acquired a deep insight into the doctrine of fluxions, upon which he afterwards published a work, which is even now regarded as among the best, if not the very best, existing in our language. After he had given up astrology, and its emoluments, he found himself reduced to great straits, notwithstanding his industry to provide a subsistence for his family at Derby; and on that account he determined to remove to London, which he did in the year 1736. When he arrived at the capital, unknown and without recommendation, he for some time followed his business in Spitalfields, and taught mathematics in the evening, and at other spare hours. His exertions were attended with such success, that he returned to the country, and brought to town his wife, with her three children. The number of his scholars increased, and he was encouraged to make proposals for publishing by

subscription

subscription "A New Treatise of Fluxions." The book was printed in 1737. In the year 1740 he published "A Treatise on the Nature and Laws of Chance." This is a very thin and small quarto; and to this treatise are annexed full and clear investigations of two important problems, added to the second edition of De Moivre's Book of Chances, as also two new methods for the summation of series. Mr. Simpson's next publication was a volume, in quarto, of "Essays on several curious and interesting Subjects in speculative and mixed Mathematics," printed in 1740. Soon after the publication of this book, he was chosen member of the Royal Academy at Stockholm. This was followed by a smaller volume, on "The Doctrine of Annuities and Reversions, deduced from general and evident Principles, with useful Tables, shewing the Values of single and joint Lives." Next year came out an "Appendix, containing Remarks on De Moivre's Book on the same Subject, with Answers to some personal and malignant Representations in the Preface to it." In 1743 he published his "Mathematical Dissertations on a variety of physic and analytical Subjects." Shortly after this he published "A Treatise on Algebra," which in the year 1755 he enlarged and considerably improved. After this he gave the public his "Elements of Geometry," with their application to mensuration, to the determination of maxima and minima, and to the construction of a great variety of geometrical problems. This work has passed through many editions, and is still read in some places devoted to the education of the young; though we think it has been superseded by other treatises of more modern date. The first edition of this book occasioned some controversy between Mr. Thomas Simpson and Dr. Robert Simson, the author of a well-known edition of Euclid's Elements. See SIMSON.

In the year 1748, Mr. Simpson published "Trigonometry, plane and spherical, with the Construction and Application of Logarithms." In 1750 he published a new edition of his "Treatise on Fluxions," which, however, he wished to be considered rather as a new work than a new edition of an old one. In 1752 appeared in 8vo. a work, entitled "Select Exercises for young Proficients in Mathematics;" and in 1757 he published his last work, entitled "Miscellaneous Tracts,"—"which," says Dr. Hutton, "was a valuable bequest, whether we consider the dignity and importance of the subjects, or the sublime and accurate manner in which they are treated." Such are the scientific works of Mr. Simpson. Through the interest of Mr. Jones, the father of the celebrated sir William Jones, Mr. Simpson was, in 1743, appointed to the professorship of mathematics, then vacant, in the Royal Academy of Woolwich; and in 1745 he was admitted a fellow of the Royal Society. On this occasion, in consequence of his very moderate circumstances, he was excused his admission fees, and from giving bond for the settled future annual payments. As a professor, he exerted all his talents in instructing the pupils committed to his care. He had, it has been said, a peculiar and happy method of teaching, which, united to a great degree of mildness, engaged the attention, and conciliated the esteem and friendship of his scholars. Mr. Simpson died in the year 1761, in the 51st year of his age. Besides the works already mentioned, he wrote several papers, which were read before the Royal Society, and printed in their Transactions. He was not only a contributor to, but for some years editor of, the Lady's Diary, during which, viz. from the year 1754 to 1760, he raised that work to a high degree of respectability. In 1760, when a plan was in agitation for erecting Blackfriars bridge, he was consulted

by the committee in regard to the best form for the arches. On this occasion he preferred the femicircular form; and besides his report to the committee, he wrote some letters on the subject, which were afterwards published in the Gentleman's Magazine.

SIMPSON, JOHN, was born at Leicester, in the month of March 1746. He was educated for the ministry among the Protestant dissenters, under the care of Mr. (afterwards Dr.) John Aikin, who kept a flourishing school at Kibworth, in Leicestershire, and afterwards an academy at Warrington, for the education of young men devoted to the ministry. From Warrington Mr. Simpson went, in 1765, to Glasgow, where he spent two years in this ancient seat of learning, and where he attended the lectures of the excellent Dr. Leechman. At Glasgow he remained two years, when he pursued his studies in a private manner among his relations, till the month of April 1772, when he settled at Nottingham, and from thence removed, in 1777, to Walthamflow, where he became pastor of the congregation of dissenters, which had previously enjoyed the joint services of Mr. Farmer and Mr. Radcliffe. Here he remained but two years, and after this it does not appear that he was settled any where as minister, but continued preaching occasionally to the end of his life. As a preacher he acquired considerable reputation, but he is chiefly known as a critic on the Holy Scriptures. His principal work is entitled "Essays on the Language of Scripture," in two volumes octavo. Besides this he published many other works, among which are "An Essay to shew that Christianity is best conveyed in the Historic Form;" "A View of the internal and presumptive Evidences of Christianity," which is a most useful performance, and it has been said may be ranked, in merit and value, with the moral demonstrations of the truth of the Christian religion of Taylor, Locke, Lardner, Clarke, and Paley. Mr. Simpson died in the year 1813. He was an Unitarian in the largest sense of the word; and agreeably to the enlightened, conscientious, and general consistency of his character, his speculative belief inspired him with the most genuine sentiments of rational piety, and an elevated devotion. He was firm in his principles, steady in his conduct, and courteous in his manners; modest, humble, affectionate, disinterested, and generous. See Sermons on the Death of Mr. Simpson, by the Rev. T. Jervis and the Rev. — Hunter.

SIMPSON, CHRISTOPHER, an English musician of the seventeenth century, extremely admired for his performance on the viol da gamba, or six-stringed-bass, and general knowledge of music. The bass-viol with six strings, and a fretted finger-board, was in such general favour in his time, that almost all the first musicians of our country, whose names are come down to us, were performers upon it, and composed pieces purposely to shew its powers; but particularly Coperario, William Lawes, Jenkins, Dr. Colman, Lupo, Mico, and Loosmore.

Simpson, during the last years of the Usurpation, published a treatise on this instrument, entitled "The Division Violin, or an Introduction to the playing upon a Ground." But this instrument, like the lute, without which no concert could subsist, was soon after so totally banished, that its form and construction were scarcely known, till the arrival of Abel in England, whose taste, knowledge, and expression upon it were so exquisite, that, instead of renovating its use, they seem to have kept lovers of music at an awful distance from the instrument, and in utter despair of ever approaching such excellence. The instrument itself, however, was so nasal, that this great musician, with all his science and power of hand, could not prevent his most enthusiastic

thusiastic admirers from lamenting that he had not, early in life, applied himself to the violoncello.

But if its general use had continued, or were restored, this book of Simpson, from the universal change of taste and style of every species of music, would be of but little use to a student on that instrument now; when rapid divisions, of no other merit than the difficulty of executing them, have been totally supplanted by vocal expression, learned modulation, and that rich harmony to which the number of its strings is favourable. Rough, but warm enco-miastic verses, are prefixed to Simpson's works by Dr. Colman, John Jenkins, Mathew Lock, and others, which only shew with what perishable materials musical fame is built!

A translation of this book into Latin, for the use of foreigners, with the original text on the opposite page, was published by the author in 1665, under the title of "Chelys Minuritionum; Editio secunda," thin folio.

Besides these, Simpson published, in 1667, "A Compendium of practical Music, in five Parts, containing 1. The Rudiments of Song. 2. The Principles of Composition. 3. The Use of Discord. 4. The Form of Figurative Defcant. 5. The Contrivance of Canon."

Whoever expects to learn the whole principles of an art by a single book, or, indeed, any number of books, without oral instruction, or great study, practice, and experience, must be disappointed. This compendium, like most others of the kind, more frequently generates new doubts and perplexities, than removes the old. However, something is to be learned from most books; and what a student is unable to find in one, if out of the reach of a master, must be sought in another.

Simpson, in his younger days, served in the royal army, raised for Charles I. by Cavendish, duke of Newcastle; he was a Roman Catholic, and patronized by sir Robert Bolles, of Leicester-Place, with whom he resided during the Interregnum. He seems to have been in close friendship with Jenkins and Lock, as, on all occasions, they reciprocally praise each other.

SIMPSON, REDMOND, an eminent performer on the hautbois. He was a natural son of Dubourg, the famous performer on the violin, and served an apprenticeship to Low, the hautbois player and copyist. Simpson, when out of his time, improved in the performance on his instrument so much, as to be thought, till the arrival of Fischer, superior to all the hautbois players of his time, except T. Vincent, the disciple of Martini. On the death of Richard Vincent, in 1777, first hautbois, during more than thirty years, of Covent Garden playhouse, and of Vauxhall gardens, father of the first husband of Miss Burchell, Simpson was engaged as first hautbois at Covent Garden, and in a few years rendered himself so useful in bringing out musical performances at that theatre, that he was appointed joint manager; and was an active and important personage at the meetings of the musical fund; was one of the assistant directors at the commemoration of Handel, in 1784; had a turn for business; and after ceasing to play in public, he was often useful in stating, calculating, and settling the accounts of the society, to the time of his death, in January 1787. He was buried in the cloister of Westminster Abbey, his funeral being attended by the principal professors in London.

SIMPSON, in *Agriculture*, a provincial term applied to groundsel, a troublesome weed in some soils.

SIMPSON'S *Island*, in *Geography*, a small island in the South Pacific ocean, discovered by captain Carteret in 1767; 4 miles W. from Carteret island. S. lat. 8° 26'. E. long. 159° 20'.

SIMPULUM, among the Romans, a vessel with a long handle, and made like a cruet. It was used in sacrifices and libations, for taking a very little wine at a time.

SIMRAR, in *Geography*, a town of Hindooستان, in Oude; 24 miles E.S.E. of Fyzabad.

SIMREE, a town of Bengal; 32 miles N.N.W. of Boglipur.

SIMSAT, a town of Asiatic Turkey, in the government of Diarbekir; 54 miles W. of Diarbekir.

SIMSBURY, a post-town of America, in Hartford county, Connecticut; 14 miles N.W. of Hartford. Copper-ore has been found in this place. It contains 1966 inhabitants; 386 miles from Washington.

SIMSIA, in *Botany*, so called by Mr. Brown, is a just tribute to the botanical learning and skill of Dr. John Sims, F.R.S. and F.L.S. the continuator, since the fourteenth volume, of the popular and very useful *Botanical Magazine*, of the late Mr. WILLIAM CURTIS; see that article.—Brown Tr. of Linn. Soc. v. 10. 152. Prodr. Nov. Holl. v. 1. 367.—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Proteaceæ*, Juss. Brown.

Gen. Ch. *Cal.* none, unless the corolla be taken for such. *Cor.* Petals four, inferior, linear-oblong, equal, deciduous; reflexed at the extremity. Nectary none. *Stam.* Filaments four, awl-shaped, prominent, inserted into the disk of each petal; anthers roundish, cohering, so that the adjoining lobes of each make one common cell, at length separating. *Pist.* Germs superior, obovate; style cylindrical; stigma dilated, concave. *Peric.* Nut inversely conical, of one cell, naked.

Ess. Ch. Petals four, equal, reflexed, without nectariferous glands. Stamens prominent. Anthers cohering, their adjoining lobes making a common cell. Stigma dilated, concave. Nut inversely conical.

A New Holland genus of smooth shrubs, of humble growth. *Leaves* alternate, thread-shaped, forked; their *footstalks* dilated at the base. *Flowers* small, yellow, smooth, composing small, globose, terminal heads, disposed either in clusters or panicles, with or without a short common *involucrum*, and with a minute *bractea* under each flower. Two species only are mentioned.

1. *S. tenuifolia*. Slender-leaved Simsia.—Heads naked, mostly solitary on each branch of the panicle, accompanied by small partial bracteas.—Found by Mr. Brown, on stony sides of hills, in Lewin's land, on the south coast of New Holland.

2. *S. anethifolia*. Fennel-leaved Simsia.—Heads numerous in each panicle, and about as long as its partial branches, accompanied by imbricated involucral leaves.—Gathered by Mr. Brown, on the sandy sea-shores of the same country.

SIMSKALA, *Oster and Wester*, in *Geography*, two small islands in the Baltic, E. of Aland, about four miles apart. N. lat. 60° 21'. E. long. 20° 8'.

SIMPSON, ROBERT, in *Biography*, was born in the year 1687, of a very respectable family, in the county of Lanark. He was educated in the university of Glasgow, where he made great progress in his studies, and acquired in every branch of science a large stock of information, which, if it had never been greatly augmented afterwards, would have done great credit to any professional man. He became, at an early period, an adept in what was denominated the philosophy and theology of the schools, and was able to supply with great credit the place of a sick relation in the class of Oriental languages. While he was pursuing a course of theology, as preparatory to his entering into orders, mathematics took hold of his fancy, and he would, in after-life, fay

say that he amused himself in his favourite pursuit, while he was actually preparing his exercises for the divinity hall. When fatigued with speculations, in which he could not meet with certainty to reward his labours, he relieved his mind, ardent in the pursuit of truth, by turning to mathematics, with which he never failed to meet with what would satisfy and refresh him. For a long time he restricted himself to a very moderate use of the cordial, fearing that he should soon exhaust the stock which so limited and abstract a science was capable of yielding; at length, however, his fears were dissipated on this head, for he found that the more he learned, and the farther he advanced, the more there was to learn, and a still wider field opened to his view. He accordingly determined to make the mathematics the profession of his life, and gave himself up to the study without reserve. It is said, that his original incitement to this science as a treat, as something to please and refresh the mind in the midst of severer tasks, gave a particular turn to his mathematical pursuits, from which he could never deviate. He devoted himself chiefly to the ancient method of pure geometry, and felt a decided dislike to the Cartesian method of substituting symbols for the operations of the mind, and still less was he willing to admit symbols for the objects of discussion, for lines, surfaces, solids, and their affections. He was rather disposed in the solution of an algebraical problem, where quantity alone is to be considered, to substitute figure and its affections for the algebraical symbols, and to convert the algebraic formula into an analogous geometrical theorem. In so little respect did he come at last to consider algebraic analysis, as to denominate it a mere mechanical knack, in which he would say we proceed without ideas of any kind, and retain a result without meaning, and therefore without any conviction of its truth.

About the age of twenty-five Dr. Simson was chosen professor of mathematics in the university of Glasgow. He immediately went to London, and there formed an acquaintance with the most eminent men who at that time flourished in the metropolis. Among these was the celebrated Halley, of whom he always spoke with the most marked respect, saying that he had more acute penetration, and the most just taste in that science, of any man he had ever known. Dr. Simson also admired the masterly steps which sir Isaac Newton was accustomed to take in his investigations, and his manner of substituting geometrical figures for the quantities which are observed in the phenomena of nature. He was accustomed to say, that the 39th proposition of the first book of the *Principia*, was the most important proposition that had ever been exhibited to the physico-mathematical philosopher, and he used to illustrate to the higher classes of his pupils, the superiority of the geometrical over the algebraic analysis, by comparing the solution given by Newton, of the inverse problem of centripetal forces, in the 42d proposition of that book, with the one given by John Bernoulli, in the *Memoirs of the Academy of Sciences at Paris*, for the year 1713.

Returning to his mathematical chair, Dr. Simson discharged the duties of a professor, for more than half a century, with great honour to the university and to himself. It is scarcely necessary to add, that in his lectures he always made use of the geometry of Euclid, in preference to those works which he thought leaned too much to analysis. His method of teaching was simple and perspicuous, his elocution clear, and his manner easy and impressive. He uniformly engaged the respect and affection of his pupils.

It was owing to the advice of Dr. Halley that our author so early directed his efforts to the restoration of the ancient geometers. He had recommended this to him as the most

certain means of acquiring a high reputation, as well as to improve his taste, and he presented him with a copy of Pappus's *Mathematical Collections*, enriched with his own notes. The perspicuity of the ancient geometrical analysis, and the elegance of the solutions which it affords, induced him to engage in an arduous attempt, which was nothing less than the entire recovery of this method. His first task was the restoration of Euclid's *Porisms*, from the scanty and mutilated account of that work in a single passage of Pappus. He, however, succeeded, and so early as 1718, seems to have been in possession of this method of investigation, which was considered by the eminent geometers of antiquity as their surest guide through the intricate labyrinths of the higher geometry. In 1723 Dr. Simson gave a specimen of this discovery in the *Philosophical Transactions*; and after that period he continued with unremitting assiduity to restore those choice porisms which Euclid had collected, as of the most general use in the solution of difficult problems. Having obtained the object of which he was in pursuit, he turned his thoughts to other works of the ancient geometers, and the *Porisms of Euclid* had now only an occasional share of his attention. The *Loci Plani of Apollonius* were the next task in which he engaged, and which he completed in the year 1738; but after it was printed he was far from being satisfied that he had given the identical propositions of that ancient geometer; he withheld the impression several years, and it was with extreme reluctance that he yielded to the entreaties of his mathematical friends in publishing the work in 1746, with some emendations, in those cases in which he thought he had deviated the most from the author. Anxious for his own reputation, and fearing that he had not done justice to Apollonius, he soon recalled all the copies that were in the hands of the booksellers, and the impression lay by him several years. He afterwards revised and corrected the work, and even then did not, without some degree of hesitation, allow it to come into the world as the restoration of Apollonius. The work was, however, received by the public with great approbation; the author's name became better known; and he was now considered as among the very first and most elegant geometers of the age. He had, previously to this, published his *Conic Sections*, a treatise of uncommon merit, whether considered as a complete restitution of the celebrated work of Apollonius Pergæus, or as an excellent system of this useful branch of mathematics. This work was intended as an introduction, or preparatory piece, to the study of Apollonius, and he has accordingly accommodated it to this purpose. The intimate acquaintance which Dr. Simson had now acquired with all the original works of the ancient geometers, as well as with their commentators and critics, encouraged him to hope that he should be able to restore to its original state that most useful of them all, the *Elements of Euclid*, and under the impression of this idea, he began seriously to make preparation for a new and more perfect edition. The errors which had crept into this celebrated work appeared to require the most careful efforts for their extirpation; and the data also, which were in like manner the introduction to the whole art of geometrical investigation, seemed to call for the noblest exertions of a real master in the science. The data of Euclid have fortunately been preserved, but the work was neglected, and the few ancient copies, which amount only to three or four, are said to be wretchedly mutilated and erroneous. It had, however, been restored, with some degree of success, by previous authors; but Dr. Simson's view of the whole analytical system pointed out to him many parts which still required amendment. He therefore made its restitution a joint task with that of the *Elements*, and all

lovers of geometry are ready gratefully to acknowledge their obligations to him for his edition, which contains the Elements and the Data, and which has gone through many impressions in quarto and octavo, in the Latin and English languages.

Another work on which Dr. Simson bestowed great labour and pains, was the Sectio Determinata of Apollonius, which, though begun early, was not given to the world till after his death, when it was printed with the work on Porisms of Euclid, at the expence of the late earl Stanhope, who was himself deeply read in mathematics, and who for many years had kept up a constant correspondence with Dr. Simson; and at the death of the professor, in 1768, the noble lord engaged Mr. Clow, professor of logic in the university of Glasgow, to whose care he had left all his papers, to make a selection of such as might serve to support and extend his well-earned reputation as the restorer of ancient geometry.

“The life of a literary man,” says his biographer, “sceldom marked with much variety; and a mathematician immersed in study, is more abstracted, perhaps, than any other person from the ordinary occurrences of life, and even the ordinary topics of conversation. Such was the case with Dr. Simson. As he never entered into the marriage state, and had no occasion for the commodious house in the university, to which as professor he was entitled, he contented himself with chambers, spacious enough for his own accommodation, and for containing his large, but well-selected, collection of books, but without any decoration, or even convenient furniture. His official servant acted as valet, footman, and bed-maker; and as this retirement was entirely devoted to study, he entertained no company at his chambers, but on occasions, when he wished to see his friends, he repaired to a neighbouring house, where an apartment was kept sacred to him and his guests. He enjoyed a long course of uninterrupted health, but towards the close of life he suffered from acute disease, which obliged him to employ an assistant in his professional labours. He died in 1768, at the age of 81, leaving to the university his valuable library, which is now kept apart from the rest of the books. It is still regarded as the most complete collection of mathematical works and manuscripts in the kingdom, many of them being rendered doubly valuable by the addition of Dr. Simson’s notes. It is open for the public benefit, but the use of it is limited by particular rules and restrictions. Dr. Simson was of a good stature, and he had a fine countenance, and even in his old age he retained much gracefulness and dignity of manner. He was naturally disposed to cheerfulness; and though he seldom made the first advances towards acquaintance, he always behaved with great affability to strangers.” See Dr. William Trail’s Account of the Life and Writings of Dr. Simson.

**SIMULACRUM**, among the Romans. See **IDOL** and **IDOLATRY**.

**SIMULATION**, in *Ethics*, is making a thing appear which does not exist; and thus it is distinguished from *disimulation*, which is keeping that which exists from appearing. See **DISSIMULATION**.

**SIMULCANDY**, in *Geography*, a town of Bengal; 60 miles N.E. of Pucculoe.

**SIMULYA**, a town of Bengal; 25 miles N.N.E. of Dacca.

**SIMUS**, in *Ichthyology*, the name used by some authors for the naseus, or nase, a fish common in the large rivers in Germany, and somewhat resembling our chub, and in some respects our common rudd.

**SIMYRA**, **SUMRAH**, in *Ancient Geography*, a town of

Syria, situated on a plain two leagues N. of mount Libanus, and eight leagues S.S.E. of Antaradus, and  $1\frac{1}{2}$  league S. of the river Ker. Strabo says that it was inhabited by the Zemarites. Ptolemy places it between the mouth of the rivers Eleutherus and Orthofia.

**SIN**, the kingdoms of Laos and Camboja, an extensive country of India, on the other side of the Ganges, according to Ptolemy.

**SIN**, or *Zin*, a city and desert S. of the Holy Land, in Arabia Petraea: this gave name to the wilderness of Sin. The scripture distinguishes two cities and two deserts of Sin; one is written  $\text{סין}$ , *Sin*, with a samech, and the other  $\text{סנין}$ , *tsin*, with a tzade. The first was near Egypt and the Red sea. The Israelites, in their march, entered the wilderness of Sin immediately after they had passed the sea, between Elim and Sinai. (Exod. xvi. 1. and xvii. 1.) Here the manna descended upon them. The other Sin was south of Palestine, but towards the Dead sea. Kadesh was in the desert of Zin (Deut. xxii. 51.); from this wilderness they sent out the spies. Here Moses and Aaron offended the Lord, at the waters of strife. (Numb. xiii. 21.) The land of Canaan, and the tribe of Judah, had the desert of Zin, or Zina, for their southern limit. Numb. xxvii. 14. xxxiv. 3. Josh. xv. 3.

**SIN**, in *Theology*, denotes want of conformity to the law of God, given as a rule to the reasonable creature, and so far as any creature is capable of conforming to it, in the things which that law requires, or the transgression of that law in those things which it forbids; and under this definition are comprehended both the sins of *omission* and sins of *commission*.

Plato defines sin to be something void, both of number and measure: by way of contradiction to virtue, which he makes to consist in musical numbers, &c. See **VIRTUE**, and **RHYTHMUS**.

Accordingly, Suarez observes, that an action becomes sinful, by its wanting a due commensuration; for as every thing measured refers to some rule, from which, if it deviate, it becomes incommensurate; and as the rule of man’s will is the law of God, &c. Suarez adds, that all evil actions are prohibited by some divine law; and that this is required to the perfection of the divine providence.

Simplicius, and after him the schoolmen, assert, that evil is not any positive thing, contrary to good; but a mere defect and accident.

Sins are distinguished into *original* and *actual*.

**SIN**, *Original*, has been divided by some divines into *inherent* and *imputed*: the former term is used to denote that corruption or degeneracy of nature, which is said to be propagated by the laws of generation from the first man to all his offspring, by reason of which man is utterly indisposed, disabled, and made opposite unto all that is spiritually good, and wholly inclined to all evil, and that continually. Hence, it is said, proceed all actual transgressions. The general cause and ground of this propagation of a sinful nature, are referred originally to man’s common interest in the guilt or condemnation of Adam’s first sin; but the manner in which this hereditary corruption is conveyed, is not particularly explained, though some have supposed that it may result from the constitution of the body, and the dependence of the mind upon it.

Father Malebranche accounts for it from natural causes thus: men at this day retain, in the brain, all the traces and impressions of their first parents. For all animals produce their like, and with like traces in the brain; whence it is that animals of the same kind have the same sympathies and antipathies, and do the same things on the same

occasions; and our first parents, after their transgression, received such deep traces in the brain, by the impression of sensible objects, that it was very possible they might communicate them to their children.

Now, as it is necessary, according to the order established by nature, that the thoughts of the soul be conformable to the traces in the brain; it may be said, that as soon as we are formed in the womb, we are infected with the corruption of our parents: for having traces in the brain like those of the persons who gave us being, it is necessary we have the same thoughts, and the same inclinations, with regard to sensible objects. Thus, of course, we must be born with concupiscence and original sin. With concupiscence, if that be nothing but the natural effort the traces of the brain make on the mind to attach it to sensible things; and with original sin, if that be nothing but the prevalency of concupiscence; nothing, in reality, but these effects considered as victorious, and as masters of the mind and heart of the child.

*Imputed original sin* denotes that guilt or obligation to punishment, to which all the posterity of Adam are subject, by the imputation of his transgression. This is called the guilt of Adam's first sin, in which the sinfulness of that state into which man fell is laid partly to consist; and it is denominated *original sin*, in order to distinguish it from *actual sin*, or personal guilt. This doctrine of imputed guilt has been explained and vindicated by supposing a covenant made with Adam, (called by divines the "covenant of works," see COVENANT,) as a public person, not for himself only, but for his posterity, in consequence of which he became the federal head, surety, or representative of all mankind; and they descending from him by ordinary generation, sinned in him, and fell with him, in his first transgression. It has been debated, how far the imputation of Adam's sin reaches: some have maintained, that it extends to final condemnation, and eternal misery: others have suggested, that the sin of Adam has subjected his posterity to an utter extinction of being; so that all, who die in their infancy, fall into a state of annihilation, excepting those who are the seed of God's people, who, by virtue of the blessings of the covenant made with Abraham, and the promise to the seed of the righteous, shall, through the grace and power of Christ, obtain a part in a happy resurrection, in which other infants shall have no share.

It seems best to acknowledge, says Dr. Doddridge, that we know nothing certain concerning the state of infants, and therefore can assert nothing positively; but that they are in the hands of a merciful God, who, as he cannot consistently with justice and truth give them a sense of guilt for an action they never committed, so probably will not hold their souls in being merely to make them sensible of pain for the guilt of a remote ancestor, their existence in a state of everlasting insensibility (which was Dr. Ridgley's scheme) seems hardly intelligible; we must, therefore, either fall in with the above-mentioned hypothesis, or suppose them all to have a part in the resurrection to glory, which seems to put them all on a level, without a due distinction in favour of the seed of believers; or else must suppose they go through some new state of trial, concerning which the Scripture is wholly silent.

Such is the doctrine of original sin, both *inherent* and *imputed*, as some divines, eminent as scholars and theologians, have stated it. In proof of the degeneracy or depravity of human nature, they have appealed to observation and experience, and they have referred to a variety of texts of scripture, in which, according to their ideas of them, it is either implied or expressed. To those who object, that the

phenomenon of universal corruption in adult persons may be accounted for by imitation, and to want of early instruction, restraint, and discipline, they reply, that the scriptures seem to trace it to a higher source, and that children often manifest propensities towards those vices of which they have seen no examples; to which it is added, that there are many examples of eminent virtue in the world, and yet they are not so frequently, or so easily imitated, as those of a vicious nature, which plainly shews a bias on the mind towards vice. Hence they say, Pagans themselves, who have been most distinguished by their study of human nature, have acknowledged, in strong terms, an inward depravation and corruption adding a disproportionate force to evil examples, and rendering the mind averse to good. Those who maintain, that the sin of Adam is *imputed* to all who descended from him in the way of ordinary generation, allege, in proof of this opinion, that we are all born with such constitutions as will produce some evil inclinations, which we probably should not have had in our original state; which evil inclinations are represented in scripture as derived from our parents, and therefore may be ultimately traced up to the first sinful parents from whom we descended;—that infants are plainly liable to diseases and death, though they have not committed any personal transgression, which, while they cannot know the law, it seems impossible they should be capable of, (Rom. v. 12—14.);—that the seeds of diseases and death were undoubtedly derived to children from their immediate parents, and from them may be traced up to the first diseased and mortal parent, *i. e.* Adam;—that the scripture teaches us to consider Adam as having brought a sentence of death upon his whole race, and expressly says, that many were *constituted sinners, i. e.* on account of it are treated as such, (1 Cor. xv. 22. Rom. v. 12—19);—that the sin of Adam brought upon himself depraved inclinations, an impaired constitution, and at length death:—and there is no reason to believe, that if man had continued in a state of innocence, his offspring would have been thus corrupt, and thus calamitous from their birth. Hence, it has been inferred, that the covenant was made with Adam, not only for himself, but in some measure for his posterity; so that he was to be considered as the great head and representative of all that were to descend from him.

On the other hand, many divines, no less eminent as scholars and theologians, than those whose sentiments we have already stated, have disputed the validity of the arguments alleged in proof of the doctrine of original sin; and whilst some of them have disowned the doctrine *in toto*, as irrational and unscriptural, others have allowed that part of it which comprehends the depravity of the human species, but have rejected the imputation of Adam's sin to his posterity. Accordingly Limborch, rejecting and refusing the imputation of Adam's sin, acknowledges, that men are now born less pure than Adam was created, and with a certain inclination to sin; but this inclination cannot properly be called sin, or a habit of sin propagated to them from Adam; but merely an inclination to esteem and pursue what is agreeable to the flesh, arising from the bodily constitution transmitted to them by their parents. Inclinations and appetites of this kind, being most agreeable to the flesh, are contrary to the divine will, as God by prohibiting them tries the readiness of our obedience, and of course these inclinations are inclinations to sin. But, if it be asked, says this author, whether there be in human nature a certain original corruption or habit of sin propagated from Adam to his posterity, which may truly and properly be called sin, by which the understanding, and will, and all the affections

affections are so depraved, that they are inclined only to evil, and that all mankind are by nature subject to the wrath of God, such kind of corruption is consistent neither with scripture nor with right reason. The scripture, he says, teaches no such doctrine, as that which charges infants with a moral corruption, that is truly and properly sin. (See Deut. i. 39. Jonah, iv. 11. Romans, ix. 11.) Our Saviour recommends it to his disciples to be as little children. (See also 1 Cor. xiv. 20.) This notion, says Limborch, is contrary to the justice of God, who would not punish men with this moral corruption, from which all actual sins proceed, and which leads to future perdition and misery. God cannot be the author of sin. Besides, it cannot be conceived, how this sin can be propagated; it cannot belong to the mind, which proceeds immediately from God, nor can it exist in the body, which is incapable of sin. But as diseases may be propagated, so may a peculiar temperament or constitution, and together with this an inclination to certain objects, which, immoderately indulged, may become sinful, but is not sinful in itself. Moreover, no sin is liable to punishment, which is involuntary; but original corruption is involuntary. Limborch explains many texts, and refutes many arguments urged by the advocates of original sin. Another writer, (Dr. Taylor,) who has taken a lead in this controversy, on the same side of the question, proceeds, in the examination of the doctrine of original sin, upon the same plan with Dr. Clarke, in his "Scripture Doctrine of the Trinity," by citing and explaining all those passages of scripture which expressly speak of the consequences of the first transgression. He observes, that the consequences of the first transgression are spoken of certainly and plainly but five times in the whole bible, twice in the Old, and thrice in the New Testament. The first passage is Gen. ii. 17. In this passage, he says, death is opposed to life, and must be so understood. But not one word occurs in this text relating to Adam's posterity. 2. The consequences of the transgression of Adam and Eve are related in Gen. iii. from the 7th verse to the end of the chapter. The natural consequences were shame and fear, the common effects of guilt, which was personal, and could belong only to themselves. The judicial consequences pertained either to the serpent, the woman, or the man. As far as they relate to the man, Adam became obnoxious to death, which, as our author conceives, was death in law, or eternal death; and if the law had been immediately executed, his posterity then included in his loins must have been extinct. But it is alleged, that there is not a word of a curse upon the souls of our first parents, *i. e.* upon the powers of their minds; nor does the least intimation occur with respect to any other death, besides that dissolution which all mankind undergo, when they cease to live in this world. It is also observed, that we, their posterity, are in fact subject to the same afflictions and mortality here inflicted by sentence upon our first parents; but they are not inflicted as punishments for their sin, because punishment includes guilt; but we neither are, nor in the nature of things could be, guilty of their sin. We may suffer by their sin, and actually do suffer by it; but we are not punished for their sin, because we are not guilty of it; and this suffering is eventually a good. Accordingly it appears evident in our world, that the increase of natural evil (at least in some degree) is the lessening of moral evil.

3. The third text occurs in the New Testament, *viz.* 1 Cor. xv. 21, 22. Here it is said, the death from which all mankind shall be released at the resurrection, is the only death that came upon all men in consequence of Adam's sin; that as all men die, all men are mortal; all lose their

life in Adam, and from him our mortality commences; and it is equally undeniable, that by Christ came the resurrection of the dead. From this place we cannot conclude, says our author, that any other evil or death came upon mankind in consequence of Adam's first transgression, besides that death from which all mankind shall be delivered at the resurrection, whatever that death be.

4. The most difficult passage is that which occurs in Rom. v. 12—19. A popular advocate of the doctrine of original sin (Dr. Watts) thinks, that Adam's being a federal head, and our deriving a sinful nature from him, may be collected from this text. In this passage our author apprehends that the apostle is speaking of that death which takes place with regard to all mankind, when the present life is extinguished; and that by judgment to condemnation, or a judicial act of condemnation, the apostle means the being adjudged to the fore-mentioned death. The words "as by one man's disobedience many were made sinners," are (says Dr. Taylor) of the same signification with those in the foregoing verse, "as by the offence of one judgment came upon all men to condemnation;" and therefore they mean nothing more nor less than that by one man's disobedience, the many, that is, mankind, were made subject to death by the judicial act of God. The apostle, being a Jew, was well acquainted with the idiom of the Hebrew language; and according to that language, "being made sinners" may very well signify being adjudged or condemned to death. (See Exod. xxii. 9. Deut. xxv. 1. 1 Kings, viii. 32. Job, ix. 20. x. 2. xxxii. 3. xxxiv. 17. xl. 8. Pl. xxxvii. 33. xciv. 21. Prov. xvii. 15. II. l. 9. liv. 17.) In the Greek text it is not *γενωτες*, became sinners, but *κατασταθησαν*, were constituted sinners; *viz.* by the will and appointment of the judge. Besides, it is here expressly said, that the many, *i. e.* mankind, are made sinners, not by their own disobedience, but by the disobedience of another man; and therefore they can be sinners in no other way than as they are sufferers. Upon the whole our author thinks it plain, that "by one man's disobedience many were made sinners," means that by Adam's offence, the many, *i. e.* mankind, were made subject to death by the judgment of God. In this passage there is an evident contrast or comparison between something which Adam did and its consequences, and something which Christ did and the consequences of that: by the former the many, *i. e.* all men, are brought into condemnation; and by the latter, all men are justified unto life. The whole of the apostle's argument and assertion are supposed by our author to rest upon two principles; *viz.* that it is by the one offence of Adam that death passed upon all men, and not by their own personal sins; and again, that it is by the obedience of one, or the one act of Christ's obedience, (in his sufferings and death upon the cross,) that all men are justified unto life, and not by their own personal righteousness. He adds, that throughout the whole paragraph, the apostle says nothing of any federal relations or transactions either on the part of Adam or Christ, nor of our deriving a sinful nature from Adam.

5. The text 1 Tim. ii. 14. declares a fact, with regard to Eve, which needs no explanation.

Dr. Taylor, in the second part of his book, proceeds to examine other passages of scripture, which some divines have applied to original sin. We shall here select two or three of the principal, that our readers may be able to form a judgment for themselves; one is Ephes. ii. 3. "and were by nature the children of wrath even as others." The apostle, our author apprehends, cannot mean that they were liable to divine wrath or punishment by that nature which they brought into the world at their birth. For this nature,

whatever infirmities belong to it, is no other than God's own work or gift; and he thinks, that to assert that the nature which God gives us is the hateful object of his wrath, is little less than blasphemy against our good and bountiful Creator. In his address to the Ephesians, the apostle is not speaking of their nature, or the natural constitution of their souls and bodies as they came into the world, but evidently of the vicious course of life they had led among the Gentiles. Nature frequently signifies an acquired nature, which men bring upon themselves by contracting either good or bad habits. Besides, by nature may here signify really, properly, truly; for *τεκνα*, children, strictly signify the genuine children of parents by natural generation; and figuratively the word denotes relation to a person or thing by way of friendship, regard, imitation, obligation, &c.; so that "children of wrath" are those who are related to wrath, or liable to rejection or punishment. The Ephesians, as the apostle tells them, were *τεκνα θυτων*, natural genuine children of wrath, not by natural birth, or the natural constitution of their bodies or souls, but they were related to wrath in the highest and strictest sense, with regard to sin and disobedience:—Nature, in a metaphorical expression, signifying that they were really and truly children of wrath, *i. e.* stood in the strictest and closest relation to suffering.

Another passage, sometimes referred to in connection with this subject, *viz.* Rom. viii. 7, 8, contains not so much as a single word that can carry our minds to Adam, or any consequences of his sin upon us.

Gen. vi. 5. expresses the universal wickedness of the old world, but does not so much as intimate that our nature is corrupted in Adam; for the historian doth not charge their sin in any way upon Adam, but upon themselves: and besides, Noah is exempted out of the number of the corrupt and profligate; but this could not have been the case if the alleged text is a good proof that by Adam's transgression the nature of all mankind is corrupted.

Another text, which has been considered as of great importance in this controversy, is Pf. li. 5, 6. "I was shapen in iniquity, and in sin did my mother conceive me." The word *הווללתני*, which we translate *shapen*, signifies, says our author, to bring forth or bear. (If. li. 2. Prov. viii. 24, 25.) Again, the word *יתכתני* conceived me, properly signifies *warmed me*; and the expression conveys the idea, not of his being conceived, but warmed, cherished, or nursed by his mother, after he was born. Accordingly, the verse is thus translated, "Behold, I was born in iniquity, and in sin did my mother nurse me;" which has no reference to the original formation of his constitution, but is a periphrasis for his being a sinner from the womb, and is as much as to say, in plain language, I am a great sinner; or I have contracted habits of sin. This, it is said, is a scriptural way of aggravating wickedness. (See Pf. lviii. 3. Isaiah, xlviii. 8.) In the whole psalm there is not one word about Adam, or the effects of his transgression upon us. The psalmist is charging himself with his own sin. But if the words be taken in the literal sense of our version, then it is manifest that he chargeth not himself with his sin and wickedness, but some other person. But our limits will not allow of our enlarging farther in this way.

Dr. Taylor proceeds, in part iii. of his book, to examine and answer objections. It is asked, 1. Are we not in worse moral circumstances than Adam was? If by moral circumstances be meant the state of reason and virtue in the world, it is certain, that since Adam's first transgression, this has become very different from a state of innocence. But this is not the fault of human nature, no more than Adam's sin

was the fault of his nature, but occasioned, as his transgression was, by the abuse of it. If by moral circumstances be meant the provision and means which God has furnished for our spiritual improvement, the apostle to the Romans expressly affirms, that in or by Jesus Christ, God hath given us an abundance of grace. But if by moral circumstances be meant moral abilities, or mental powers, our author suggests, that there is no ground in revelation for exalting the nature of Adam to such a degree of purity and strength as some divines have raised it, when they affirm, that all his faculties were perfect, and entirely devoted to the love and obedience of his creator. The sequel of his history seems to be inconsistent with this notion.

It is said that man was made in the image of God; but can this be affirmed of his posterity? The image of God must be understood either of the rational faculties of his mind, or the dominion he had over the inferior creatures, by which he bore the nearest resemblance to God of any beings in this world; and not, as Dr. Taylor conceives, of holiness and righteousness, which is a right use of our spiritual faculties; because such an use of them could not be till after they were created; and this writer is of opinion, that original righteousness is as far from truth as original sin; and that to talk of our wanting that righteousness in which Adam was created, is to talk of nothing we want. Two texts, *viz.* Rom. ii. 14, 15, and Eccles. vii. 29, are cited by the Assembly of Divines in their larger Catechism, to prove, that our first parents had the law of God written in their hearts, and power to fulfil it, in opposition to their posterity, who want that righteousness in which they are supposed to have been created, and whose nature is corrupted to a lamentable degree: but if these texts speak not of our first parents, but of their posterity, and of the most corrupt part of their posterity too, it must be true, and the truth is very important, "that by nature we have the law of God written in our hearts, and power to fulfil it," as well as they; and are equally bound to be thankful to God for our being, and to glorify him by it.

We have already spoken of that moral taint and infection, which we are said to have derived from Adam; and in consequence of which we have a natural propensity to sin. This taint or infection must exist either in the body or the soul. In the soul, which immediately proceeds from God, it cannot exist; nor in the body, which, in a state separate from the soul, is inactive matter, which in itself, neither is nor can be the subject of moral good and evil. But such an infection, wheresoever it exists, or howsoever it is propagated, cannot be derived from Adam to every human being, independently of the will and operation of God; and to assert, that it is by his will and operation, is evidently to make him the author of the pollution. It is maintained, that by propagation it is not possible for parents to communicate vice; which is always the faulty choice of a person's own will, otherwise it is not vice. Children, it has been said, begin very soon to sin, and how can this fact be accounted for but upon the scheme of original sin; namely, that it is infused into their nature? To this objection it has been replied, that their early sin is owing to the early want of instruction and discipline. Another objection, which is strongly urged by the advocates of original sin, is this: Adam was a common or federal head and representative of all his posterity, and consequently all his offspring sinned in him, as their root; just as Levi is said to pay tithes in Abraham (Heb. vii. 9.) and as the branches must be morally corrupt, if the root be in that state. (Rom. xi. 16.) To the arguments deduced from the first of these passages it has been replied, that neither the case of Abraham and Levi,

Levi, nor the apostle's argument grounded upon it, have any manner of relation to partaking in guilt, or contracting moral corruption : and it is alleged, that the inference deducible from the second passage would be very just, if the apostle were here speaking of moral holiness, of holiness, as it is a quality or principle in the mind : whereas the holiness here mentioned is said to be that external, relative holiness which is frequently attributed to the whole nation of the Jews, as they were God's peculiar church and people. The notion of a federal head or representative of moral conduct, a representative, the guilt of whose actions shall be imputed to us, and whose sin shall corrupt and debauch our minds, and this representative appointed by God himself, is, as its opponents maintain, not only without foundation in scripture, but in itself a great absurdity. Indeed, the external circumstances of posterity may be affected by the bad conduct of their ancestors. This is frequently affirmed in scripture, and certainly holds good in the case of Adam and his posterity ; and may be a constitution, just, wise, and answering very good purposes. But that any man should represent me, that when he is guilty, I am to be reputed guilty, when he transgresseth, I shall be accountable and punishable for his transgression ; and this before I am born, and consequently before I am in any capacity of knowing, helping, or hindering what he doth ; this, I say, every one who uses his understanding must clearly see is false, unreasonable, and altogether inconsistent with the truth and goodness of God. And, if you please, you may see him fully vindicated by the spirit of truth from all injustice of this kind in Ezekiel, xviii. 20. where he affirms, "that the soul that sinneth, it shall die. The son," however he may come under disciplinary visitations, "shall not bear the iniquity of the father ; neither shall the father bear the iniquity of the son ; the righteousness of the righteous shall be upon him, and the wickedness of the wicked shall be upon him." And v. 30. "that God will judge every one according to his ways." It is further alleged, that the imputation of sin, so far as to make the posterity guilty of and chargeable with the sin of the parent, is no scriptural notion. An action, indeed, is often said to be imputed, reckoned, or accounted to a person ; but then it is no other than his own act and deed which is so accounted or imputed to him, either for righteousness or sin. See Gen. xv. 6. Lev. xvii. 3, 4. Numb. xviii. 26, 27. 1 Sam. xi. 2. 1 Sam. xxii. 15. 2 Sam. xix. 19. Prov. xxvii. 14. Pf. xxxii. 2. Pf. cvi. 31. Rom. ii. 16. Rom. iv. 3, &c. Rom. v. 13. 1 Cor. xiii. 5. 2 Cor. v. 19. Gal. iii. 6. 2 Tim. iv. 16. James, ii. 23.

We might here introduce some arguments for, and some objections to, the doctrine of original sin, of a general nature, if our limits would allow. We can only suggest, on the part of its advocates, that original sin is necessary to account for the being of sin in the world. How comes it to pass, that there is so much wickedness in the world, if our nature be not sinful?—How is it consistent with the justice of God, that we suffer at all on account of Adam's sin? Besides, it has been a generally received opinion, that the fall, corruption, and apostacy in Adam, have been the reason why Christ came into the world, and gave himself a ransom for us. To the question concerning regeneration, which is insisted upon in the New Testament, why must we be born again? it is replied, because we are born in sin. Our nature in Adam is corrupted, and utterly indisposed, disabled, and made opposite to all that is spiritually good, and wholly inclined to all evil, and that continually ; therefore we must be born again, before we can do any thing that is good and pleasing to God.

On the other hand, the opposers of this doctrine allege,

that it is highly injurious to the God of our nature to believe that our nature is originally corrupted in the manner which this doctrine supposes. To disparage our nature, is, they say, to disparage the work and gifts of God. They also suggest, that the doctrine of original sin teaches men to transfer their sin to a wrong cause, to Adam rather than to themselves ; and also that the doctrine, as it is commonly held, has a manifest tendency to propagate a notion that they must be necessarily vicious, and that it is thus destructive of virtue. They say, that to represent sin as *natural*, as altogether *unavoidable*, is to embolden men in sin, and to give not only an excuse, but a reason for sinning. They also intimate, that to charge Christianity with teaching this doctrine, is to sink its credibility ; and that it is injurious in another way, by perplexing the mind, and rendering all religious principles uncertain. "We are made," as one of them expresses it, "sinners we know not how, and therefore must be sorry for, and repent of, we know not what. We are made sinners in an arbitrary way, and we are made saints in an arbitrary way : but what is arbitrary can be brought under no rules." They think that it is not expedient or desirable to teach children, that they are born children of wrath, that they came into the world under God's curse, and that their being, as soon as given, is in the worst and most deplorable state of corruption. Young people are exhorted to remember their creator ; but how, it is said, can they remember him, without the utmost horror, who, it is supposed, hath given them life under such deplorable circumstances?

We shall close this article with a brief account of the "Fall of Man," and its consequences, as they have been stated by different divines. Adam was created, as the Assembly of Divines affirm, after God's own image, in knowledge, righteousness, and holiness, having the law of God written in his heart, and power to fulfil it ; and for proof of this assertion, they refer to Gen. ii. 27. Col. iii. 10. Ephes. iv. 24. Rom. ii. 14, 15. Eccl. vii. 29. This state of moral rectitude, or original righteousness, in which he was created, is thus described by Dr. Watts. "His reason was clear, and sense, appetite, and passion were subject to it, his judgment uncorrupted, his will had an inward, constant, superior bias, bent, and propensity to holiness and virtue ; he had an inward inclination to please and honour God, supreme love to his creator, a zeal and desire to love him, a holy fear of offending him, with a readiness to do his will." When Adam sinned he lost this moral rectitude ; and not only so, but his posterity became morally corrupt. We have already stated the opinion of the opponents to the doctrine of original sin, concerning the moral condition of Adam before his fall. By the advocates of this doctrine, it is further maintained, that a covenant was made with Adam, as a public person, not for himself only, but for his posterity ; and therefore all mankind, descending from him by ordinary generation, sinned in him, and fell with him in that first transgression. (See Acts, xvii. 26. Gen. ii. 16, 17. compared with Rom. v. 12—20. 1 Cor. xv. 21, 22.) The Fall, it is said, brought mankind into a state of sin and misery. (Rom. v. 12. iii. 13.) And the sinfulness of that state into which man fell, consisteth in the guilt of Adam's first sin, the want of that righteousness in which he was created, and the corruption of his nature, &c. (See Rom. v. 12, 19. Rom. iii. 10, 20. Eph. ii. 1, 2, 3. Rom. v. 6. viii. 7, 9. Gen. vi. 5. James, i. 14, 15. Matt. xv. 19.) It is added, that the Fall brought upon mankind the loss of communion with God, his displeasure, and curse ; so that we are by nature children of wrath, bond-slaves to Satan, and justly liable to all punishments in this

this world, and in that which is to come. See Gen. iii. 8. 10. 24. Eph. ii. 2, 3. 2 Tim. ii. 26. Gen. ii. 17. Lam. iii. 39. Rom. vi. 23. Matt. xxv. 41. 46. Jude, v. 7.

On the other hand, it is alleged, that the language of man's sinfulness consisting in the guilt of Adam's first sin is unscriptural; nor, in the nature of things, can our sinfulness consist in the guilt of Adam's first sin; because, as we could not possibly commit that action in any sense, so we could not, upon account of it, become obnoxious to punishment. If the texts above cited prove that man's nature by Adam's sin is so corrupted, that man, *i. e.* men, are utterly indisposed, disabled, and made opposite to all that is spiritually good, that is, to all moral actions, pleasing and acceptable to God, and wholly and continually inclined to all manner of wickedness, they would further prove, that men are no moral agents, and that sin must be natural to us, and if natural, necessary; and if necessary, with regard to us, it is no sin, with regard to us, or so far as we are concerned in it. For a further account of the state of this controversy, and of the arguments adduced for and against the doctrine of original sin, we refer to the Assembly's Catechism; Watts's *Ruin and Recovery*; Jennings's *Vindication*, &c. Chandler's *Sermons*, vol. iv. *Serm. 1—7*. Bury-Street *Lect.* vol. i. *Limborch Theolog. lib.* iii. c. 4. § 1, 2. The Romish casuists distinguish *actual* sins into *mortal*; which are such as make us lose the grace of God; and *venial*, which alone are pardoned, as being only sins of infirmity, not of malice. See *POPERY*.

Divines are not yet agreed what the sin against the Holy Ghost is. See *BLASPHEMY against the Holy Ghost*.

*SIN*, *Philosophical*, according to the doctrine of the Jesuits, is an action, or course of action, that is repugnant to the dictates of reason, and yet not offensive to the Deity.

*SINA*, in *Ancient Geography*, a town of Asia, in Margiana. Ptolemy.—Also, a town of Cappadocia, in the prefecture of Cilicia. *Id.*—Also, a place in the isle of Lesbos. Strabo.

*SINA*, or *Justinianopolis*, a town of Asia, in the Greater Armenia.

*SINAAB*, in *Geography*, a town of Algiers, in the province of Tremecen, on the E. side of the Shelliff; 72 miles S.W. of Algiers.

*SINACA*, in *Ancient Geography*, a town of Hyrcania. Ptolemy.

*SINADIZAVA*, in *Geography*, a town of European Turkey, in Bulgaria, on the Ozma; 12 miles E. of Nicopoli.

*SINÆ*, in *Ancient Geography*, a people of India, according to Ptolemy. It appears that their country extended from Siam into a part of China.

*SINAI*, *MOUNT*, in *Geography*, a famous mount of Arabia Petræa, on which God gave the law to Moses. (Exod. xix. 1. xxiv. 16. xxxi. 18. xxxiv. 2. 4. &c. Levit. xxv. 1. xxvi. 46.) It is situated in a kind of peninsula, formed by the two arms of the Red sea, one extending N. called the gulf of Kollun; the other extending E. called the gulf of Elan. The Arabs call mount Sinai by the name of "Tor," *i. e.* the mountain, by way of excellence; or "Jebbel Mufas," the mountain of Moses; comprehending a range of mountains which rises at the interior extremity of the valley of Fazan, restricting the name of Tor Sinai to that part of the range on which the convent of St. Catharine stands; and distant about 260 miles from Cairo. The wilderness of Sinai, where the

Israelites continued encamped almost a year, and where Moses erected the tabernacle of the covenant, is considerably elevated above the rest of the country; the ascent to it is very craggy, the greater part being cut out of the rock; and then you arrive at a large space of ground, which is a plain surrounded on all sides by rocks and emences, whose length is nearly twelve miles. Towards the extremity of this plain, on the north, two high mountains appear, the highest of which is called Sinai, the other Horeb. They are both of a very steep ascent, and the ground on which they stand is inconsiderable, when compared with their height. Sinai is one-third part higher than the other, and its ascent more upright and difficult. The Greeks have cut a flight of steps up the rock. Pococke reckons 3000 of these steps to the top of the mountain, or rather bare, pointed rock. Two German miles and a half up the mountain stands the convent of St. Catharine. The body of this monastery is a building 120 feet in length, and almost as many in breadth. Before it stands another small building, in which is the only gate of the convent, and which remains always shut, except when the bishop is there. At other times, whatever is introduced within the convent, whether men or provisions, is drawn up by the roof in a basket, and with a cord and pulley. The whole building is of hewn stone, which, in such a desert, must have been constructed with great labour and expence. Within the walls is a small mosque for the convenience of the Arabs. This monastery belongs to Greek monks, who had in former times only a tower erected near the burning bush of Moses. But being molested by the insults and depredations of the Arabs, they petitioned the emperor Justinian to build for them a strong monastery for their future security; and the emperor is said to have complied with their request. Before the convent is a large garden, planted with excellent fruit-trees. According to the account of the Arabs, the monks enter it by a subterraneous passage. These Greek ecclesiastics are not allowed to receive an European visitor, without an order from the bishop of mount Sinai, who resides ordinarily at Cairo. When the bishop happens to be present, the gate is opened, and the convent must entertain all the Arabs who come in there; and this is a grievous charge on the poor monks, who live merely on alms, and whose provisions, which they are obliged to bring from Cairo, are often stolen by the way. The Arabs are, in general, very dangerous neighbours, as they often fire on the convent from the adjacent rocks; and seize the monks whenever they find them without the walls of the monastery, and refuse to release them without a considerable ransom.

Five hundred steps above the convent is found an excellent spring, which superstitious persons have counted miraculous, as the mountain is so high and so barren. A thousand steps higher stands a chapel dedicated to the Blessed Virgin; and 500 above this, are two other chapels, situated in a plain, which the traveller enters by two small gates of mason-work. Upon this plain are two trees, under which, at high festivals, the Arabs are regaled at the expence of the Greeks. Sinai is held in great veneration, on account of the law which God gave on this mountain. The whole mountain is a very remarkable rock of red granite, interspersed with spots, to which soil has been brought by human labour, or washed down by rain, and in which grow almond-trees, figs, and vines. Mount Horeb stands W. of Sinai, so that at sunrise the shadow of Sinai covers Horeb. Beside the little fountain at the top of Sinai, there is another at the foot of Horeb, which supplies the monastery of St. Catharine. At a small distance is shewn a stone, four or five feet high, and three broad, from which, it is pretended, Moses caused the water

water to gush out: in this stone are twelve holes or channels, about a foot wide, from which, it is said, the water issued which the Israelites drank.

SINAI, *Knights of*. See CATHARINE.

SINALOA, in *Geography*. See CINALOA.

SI-NAN, a river of Algiers, which joins the Wed-el-Mailah, about five miles before it runs into the sea. It glides in a variety of beautiful windings, and is known by several names, according to the remarkable places which they water. Near the banks of this river, Barbarossa the Elder scattered his treasures when pursued by the victorious Spaniards, and here he made his last ineffectual effort to retard their progress.

SINANELLY, a town of Hindoostan, in Mysore; 22 miles S.W. of Bangalore.

SINAPATINGA, in *Ancient Geography*, a town of India, on this side of the Ganges, in the vicinity of the river Indus, and one of those which belonged to the Cathæi, according to Ptolemy.

SINAPIS, in *Botany*, a generic name, whose origin is lost in the obscurity of antiquity, which occurs, with slight variations in its orthography, in the works of Plautus, Pliny, and Columella. Theophrastus and Dioscorides call it Σινάπι. It is also met with under the terms *σινάπις* and *ναπι*; *πικρα το σινάπις, τους ωπαις*, from its pungency affecting the eyes. De Theis, much inclined on all occasions to recur to the Celtic, conjectures that this word comes from *Nap*, a general name in that language for all plants allied to the Radish.—Linn. Gen. 342. Schreb. 445. Willd. Sp. Pl. v. 3. 554. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 721. Prodr. Fl. Græc. Sibth. v. 2. 31. Ait. Hort. Kew. v. 4. 125. Tournef. t. 112. Juss. 238. Lamarck Illustr. t. 566. Gærtn. t. 143.—Class and order, *Tetradynamia Siliquosa*. Nat. Ord. *Siliquosa*, or *Cruciformes*, Linn. *Crucifera*, Juss.

Gen. Ch. *Cal.* Perianth inferior, spreading, divided into four, linear, concave, channelled leaves, forming a cross, deciduous. *Cor.* cruciform; of four, rounded, flat, spreading, undivided petals, with erect, linear claws scarcely the length of the calyx. Nectary composed of four ovate glands, one on each side between the shorter stamens and the pistil; and one on each side between the longer stamens and the calyx. *Stam.* Filaments six, awl-shaped, erect; the two shorter ones opposite; anthers erect, spreading, pointed. *Pist.* Germen superior, cylindrical; style the length of the germen, and height of the stamens; stigma capitate, undivided. *Peric.* Pod oblong, inflated unequally at the lower part, rough, of two cells and two valves; partition generally twice as long as the valves, large, compressed. *Seeds* numerous, globular.

Obs. *Sinapis* differs principally from *Brassica* in having a spreading calyx, and the claws of the petals erect. Crantz unites this genus with *Raphanus*.

Ess. Ch. Calyx widely spreading. Claws of the petals straight. Nectariferous glands four. Pod more or less cylindrical, the partition longer than the valves.

1. *S. arvensis*. Wild Mustard or Charlock. Linn. Sp. Pl. 933. Fl. Brit. n. 1. Engl. Bot. t. 1748. Curt. Lond. fasc. 5. t. 47. Fl. Dan. t. 753.—Pods with many angles, rugged, longer than their own two-edged beak. Leaves ovate, somewhat lyrate.—One of the most common and most troublesome European weeds in heavy moist corn lands, as well as about waste ground and hedges. It flowers most commonly in May and June, but occasionally in all open weather. *Root* annual, spindle-shaped, small, rigid. *Stem* round, striated, hispid with slightly deflexed bristles, tinged with red. *Leaves* alternate, stalked, ovate, rough,

unequally toothed; lower ones somewhat lyrate; upper sessile. *Flowers* in a terminal, clustered corymb, of a bright yellow colour. *Seeds* extremely pungent, well known under the name of Durham-Mustard.

2. *S. orientalis*. Oriental Mustard. Linn. Sp. Pl. 933. Amœn. Acad. v. 4. 280. Ait. n. 2. "Schkuhr. handb. v. 1. 264. t. 186." (*Sinapi orientale maximum, rapi folio*; Tourn. Cor. 17.)—Pods rough with reflexed bristles, and four blunt angles, compressed at the tip.—Native of the Levant, and introduced at Kew by M. Thouin in 1778, where it flowers in June and July. This annual is extremely like the last, from which indeed it differs merely in having the *Pods* rough with reflexed bristles, the *beak* only being smooth.

3. *S. brassicata*. Cabbage Mustard. Willd. n. 3. Loureir. Coelunch. 399.—Leaves obovate, smooth, toothed in a diminutive manner.—Native of China, where it is much cultivated. This plant, we are informed by Loureiro, has the habit of Cabbage or Lettuce, but in the structure of its calyx it resembles Mustard. *Stem* a foot and half high, very smooth. *Radical-leaves* oleraceous, obtuse, white-veined, on channelled stalks; *stem-leaves* oblong, mostly with two auricled appendages at the base of the stalk, upper ones sessile, lanceolate, embracing the stem. *Flowers* like those of the Common Cabbage, bright yellow. *Pod* also resembling that of *Brassica oleracea*.

4. *S. alba*. White Mustard. Linn. Sp. Pl. 933. Fl. Brit. n. 2. Engl. Bot. t. 1677. Curt. Lond. fasc. 5. t. 46. Mart. Ruit. t. 70.—Pods brittle, rugged, shorter than their own two-edged beak. Leaves pinnatifid.—Common in fields and by road-sides, flowering from June to August. The *root* and *stem* of this annual are like those of the first species. *Lower leaves* deeply pinnatifid; *upper* somewhat lyrate; all of them irregularly toothed and rough. *Flowers* yellow. *Pods* on nearly horizontal stalks, ribbed, with a very long, sword-shaped beak. *Seeds* large, globose, pale yellowish, occasionally black.

5. *S. nigra*. Common Mustard. Linn. Sp. Pl. 933. Fl. Brit. n. 3. Engl. Bot. t. 969. Woodv. Med. Bot. t. 151. Mart. Ruit. t. 51.—Pods smooth, square, close pressed to the stem. Upper leaves linear-lanceolate, entire, smooth.—A most common weed on hedge banks, waste ground, and the borders of fields, flowering in the middle of summer. *Root* annual, small. *Stem* much branched, spreading, round, smooth. *Leaves* stalked, irregularly lobed and toothed; radical ones rough; those of the stem and branches smooth and pendulous; the upper ones deflexed, entire, narrow. *Flowers* numerous, small, bright yellow. *Seeds* several, round, smooth, brown, furnishing "our common table mustard, one of the most useful and wholesome of stimulants, both in cookery and medicine."

6. *S. pyrenaica*. Pyrenean Mustard. Linn. Sp. Pl. 934. Allion. Pedem. t. 55. f. 1.—Pods striated, scabrous. Leaves runcinate, smooth.—Native of the Pyrenées, Mount Cenis, and similar situations in the south of Europe. It flowers about June. *Root* biennial. *Stem* angular, even, striated, wavy, smooth. *Leaves* runcinate; segments of the lower or radical ones toothed; those of the stem lanceolate. *Flowers* clustered, small, yellow. Willdenow considers *S. maritima* of Allioni as a variety of this species.

7. *S. pubescens*. Downy Mustard. Linn. Mant. 95. Prodr. Fl. Græc. n. 1580. Arduin Spec. v. 1. 21. t. 9.—Pods downy, erect, with a compressed beak. Leaves lyrate, villous.—Native of Sicily, flowering in June and July. *Stem* perennial, shrubby. *Leaves* obtuse. *Flowers* yellow, with undivided petals. *Pods* erect, hairy, or very downy, as indeed are all the parts of the plant.

## SINAPIS.

8. *S. hispida*. Hispid Mustard. Willd. n. 8.—Pods hispid, erect. Leaves lyrate, extremely rough. Stem hispid.—Native of Morocco. *Root* annual. *Stem* muricated with hairs. *Leaves* on stalks, pinnatifid, obtuse, toothed, the terminal lobe oblong, very large, exceedingly rough with short, rigid hairs. *Flowers* yellow. *Pods* terminating in a long, obtuse, flat beak.

9. *S. chinensis*. Chinese Mustard. Linn. Mant. 95. Willd. n. 9. Arduin. Spec. v. 1. 23. t. 10.—Pods smooth, slightly jointed, spreading. Leaves lyrate, or runcinate, somewhat hairy.—Native of China and Cochinchina, where it is extensively cultivated. It flowers in June and July. *Root* annual. *Stem* three feet in height, striated, branched. *Radical-leaves* stalked, large, wrinkled. *Flowers* whitish or yellow, in long, aggregate clusters.

10. *S. juncea*. Fine-leaved Mustard. Linn. Sp. Pl. 934. Jacq. Hort. Vind. v. 2. 80. t. 171.—Branches fasciculated. Upper leaves lanceolate, entire.—Native of Asia and China, flowering in the summer. *Root* annual, fibrous, whitish. *Stem* erect, branched, two feet high, smooth. *Radical-leaves* stalked, pinnatifid at the base, unequally serrated; upper lanceolate or oblong, sessile. *Flowers* yellow, in clusters, with the same pungency of smell as Common Mustard.

11. *S. Allionii*. Allioni's Mustard. Willd. n. 11. Jacq. Hort. Vind. v. 2. 79. t. 168.—Pods ovate-oblong, spreading. Leaves pinnatifid; segments jagged.—Native of Austria? It flowers in July. *Root* annual, white, fibrous. *Stem* solitary, round, generally smooth, but occasionally besprinkled with a few whitish hairs. *Leaves* jagged in a pinnatifid manner; the upper ones sessile; lower stalked. *Flowers* yellow, thinly scattered over upright clusters, nearly without scent.

12. *S. eruroides*. Dwarf Mustard. Linn. Sp. Pl. 934. Willd. n. 12. Jacq. Hort. Vind. v. 2. 80. t. 170.—Pods smooth, equal. Leaves lyrate, oblong, smooth. *Stem* smooth.—Native of the south of Europe, in vineyards and by way-sides, flowering in June and July. *Root* annual. *Stem* eight or nine inches high, purplish, a little angular. *Leaves* much jagged, yellowish-green. *Flowers* white, in loose spikes.

13. *S. cernua*. Pendulous Mustard. Willd. n. 13. Thunb. Japon. 261.—Pods smooth, spreading. Radical-leaf lyrate, the terminal lobe very large, ovate, cut and toothed.—Native of Japan and China. *Root* annual. Whole plant smooth. *Stem* furrowed, branched at the upper part. *Flowering branches* pendulous. *Flowers* white, in terminal clusters.

14. *S. japonica*. Japanese Mustard. Willd. n. 15. Thunb. Japon. 262.—Pods smooth, erect. Leaves jagged in a pinnatifid manner, smooth.—Native of Japan, about Jedo, flowering in May. Whole plant smooth. *Stem* herbaceous, erect, furrowed, branched. *Leaves* stalked, the upper ones less deeply pinnatifid, often toothed at the tip. *Flowers* yellowish, in very long clusters.

15. *S. incana*. Hoary-jointed Mustard. Linn. Sp. Pl. 934. Amœn. Acad. v. 4. 280. Jacq. Hort. Vind. v. 2. 79. t. 169.—Pods with two joints, erect. Leaves bipinnatifid; segments linear.—Native of France, Spain, Portugal, and Switzerland. It flowers in July. *Root* biennial, branched, acrid, having the taste and smell of *Brassica Napus*. *Stem* branched, hispid. *Leaves* on long stalks, lyrate, very hairy and hoary. *Flowers* small, yellow, in terminal, axillary clusters.

16. *S. frutescens*. Shrubby Mustard. Willd. n. 17. Ait. Hort. Kew. n. 11.—Pods linear, smooth. Lower-leaves oblong, toothed; upper lanceolate, undivided. *Stem*

smooth, shrubby.—Native of Madeira, whence it was introduced at Kew by Mr. F. Masson in 1777. It flowers from December to June. Figure and description wanting.

17. *S. radicata*. Long-rooted Mustard. Willd. n. 18. Desfont. Atlant. v. 2. 98. t. 167. Prodr. Fl. Græc. n. 1581. Fl. Græc. t. 648, unpublished.—Pods awl-shaped, torulose, spreading. Radical-leaves deeply lyrate, hispid. *Stem-leaves* pinnate. Branches twiggy, smooth.—Native of uncultivated hills at Algiers, and in Greece. *Roots* very long, tortuous, branched, thread-shaped. *Stem* hispid below, smooth above, erect, branched. *Lower-leaves* stalked, their segments alternate, remote, obtuse, unequally toothed: upper with lanceolate, acute, entire or toothed, segments. *Flowers* pale yellow, very like those of *S. juncea*.

18. *S. levigata*. Smooth Mustard. Linn. Sp. Pl. 934. Amœn. Acad. v. 4. 281. (Erysimi varietas; Herman. Parad. 155.)—Pods smooth, spreading. Leaves lyrate, smooth; upper ones lanceolate. *Stem* smooth.—Native of Spain and Portugal, flowering in June and July. *Root* annual or biennial. *Stem* and *leaves* remarkably smooth. *Flowers* large, yellow.

The Linnæan *S. hispanica*, a rare and little-known plant, Ait. n. 15, is removed to Desfontaines' new genus *Cordyllocarpus*, in Prodr. Fl. Græc. v. 2. 33.

Mr. Brown, in Hort. Kew. has, after Tournefort's example, considered *Sisymbrium tenuifolium* and *murale* of Linnæus as species of *Sinapis*. See SISYMBRIUM.

SINAPIS, in *Gardening*, contains plants of the hardy, herbaceous, annual kind, of which the species cultivated are, the white mustard (*S. alba*); and the common or black mustard (*S. nigra*).

The first sort is generally cultivated in gardens as a fallad herb, with cresses, radishes, rape, &c. for winter and spring use; in which intention it is a highly valuable plant.

In the second sort, it is the flour of the seed that affords the common mustard for the table.

*Method of Culture*.—The first sort is sown along with other small fallad herbs, at all times of the year, sometimes every week or fortnight, in a bed or border of light earth, sown generally in shallow drills very thick, covering it very thinly with earth; and in winter, and early in spring, during cold weather, in hot-beds. The herbs are always cut for use whilst in the seed-leaf, and but a few days old; otherwise they become too strong and rank-tasted for use. See SALLAD Herbs, and SMALL Sallad Herbs.

But in order to have seed of this sort for garden use, it should be sown on an open spot of ground, in March or April, either thinly in drills a foot asunder, or broad-cast all over the surface, and the plants be left to run up to stalk, when they will furnish ripe seeds in August. And in order to raise the plants for the seed for mustard, the seeds should be sown in the spring, any time in March, in some open situation, either in the kitchen-garden, or in open fields. In either case, having dug or ploughed the ground, the seed should be sown broad-cast all over the surface, and raked or harrowed in lightly; or it may be sown in shallow drills a foot asunder, and be slightly covered in. The plants soon come up; and when they have four or more leaves an inch or two broad, if they stand very thick, those sown in the broad-cast way particularly should be hoed and thinned, leaving them six or eight inches asunder, cutting up all weeds; repeating the operation once or more, if necessary. After this the plants will soon spread and cover the ground, and shoot fast up to stalks for flowers and seed, which ripens in July or August, when the stalks should be cut or pulled up, and the seed, being properly hardened,

and dried in the pod, should either be thrashed out directly, or stacked up dry, and thrashed at occasional opportunities afterwards; but the first is the best method.

*SINAPIS Nigra*, *Common Black Mustard*, in the *Materia Medica*, &c. is common in corn-fields and banks of ditches, but is cultivated for use, and flowers in June. (See *SINAPIS* and *MUSTARD*.) The seeds of this species of mustard, which are directed by the London College, and those of the *S. alba*, which are preferred by that of Edinburgh, are not different in taste or their general effects, and answer equally well for the table and for medical purposes. Their taste is acrid and pungent, and when bruised this pungency becomes volatile and affects the smell: they readily impart these qualities to aqueous liquors, and by distillation with water yield an essential oil of great acrimony; but to rectified spirits they give out very little either of their smell or taste. When subjected to the press, they yield a considerable quantity of mild insipid oil, which is as free from acrimony as that of almonds. By writers on the materia medica, mustard is considered as promoting appetite, assisting digestion, attenuating viscid juices, and by stimulating the fibres, proving a general remedy in paralytic and rheumatic affections. In considerable quantity, it opens the body and increases the urinary discharge, and hence has been found useful in dropsical complaints. In these affections, perhaps, the best mode of exhibiting mustard, is in the form of whey, which is made by boiling ʒiv of the bruised seeds in oj of milk, and straining to separate the curd. A fourth part of this quantity may be taken for a dose three times a day. It has also been recommended as an antiscorbutic; though Haller says that the use of mustard disposes the humours to putrescency, to which opinion he was probably inclined by the supposition that it contained volatile alkali; but it has been found that vegetables reckoned among the alkalescent plants may be so directed by fermentation as to be of the acerb kind, and the alkali obtained from them seems not to have existed in the vegetable in a separate state. The great pungency of these plants is therefore not to be ascribed to the volatile alkali, but to the essential oil which they contain. Bergius informs us, that he found mustard of great efficacy in curing vernal intermittents; for which purpose he directed a spoonful of the whole seeds to be taken three or four times a day, during the apyrexia; and when the disease was obstinate, he added flour of mustard to the bark. Externally these seeds are frequently used as a stimulant or sinapism. The flour rubbed on the skin, or applied in the form of a cataplasm, made into a paste with crumbs of bread and vinegar, soon excites a sense of pain, considerable inflammation, and sometimes vesication. In these forms it has been found serviceable in paralysis, and applied to the soles of the feet in the delirium of typhus, and in comatose affections. It is observed by Cullen that the fresh powder of mustard shews little pungency and much bitterness; but when it has been moistened with vinegar, and kept for a day, the essential oil is evolved, and it becomes considerably more acrid, as is well known to those who prepare mustard for the table; a circumstance which should be attended to when designed for external use. Mustard-seed may be most conveniently given entire or unbruised, and to the quantity of a spoonful or half an ounce for a dose. The constituents of mustard-seed appear to be starch, mucus, a bland fixed oil, an acrid volatile oil, and an ammoniacal salt. The officinal preparations of mustard are "cataplasma sinapis," L. D. and "emplastrum meloë compositum," E. See *PLASTER*.

The cataplasm of mustard of the Lond. Ph. is prepared by mixing mustard-seed and lint-seed, of each in powder half a pound, with a sufficient quantity of hot vinegar, to

the thickness of a cataplasm. The mustard cataplasm of the Dub. Ph. is formed of mustard-seed in powder and crumb of bread, of each half a pound, and a sufficient quantity of vinegar. This preparation may be rendered more acrid by adding two ounces of horse-radish finely scraped. These cataplasms are powerful local stimulants and rubefacients. They are to be spread on cloth to the thickness of about half an inch, and applied to the soles of the feet, in the low stage of typhus fever, particularly when stupor or delirium is present, and in apoplexy, coma, and other cases in which there is a great determination to the head. Their rubefacient effects are very quickly produced, and often so powerfully as to raise blisters on the part. Cullen's Mat. Med. Woodv. Med. Bot. Thomson's Lond. Disp.

*SINAPI Persicum*, *Persian Mustard*, a name by which some botanical authors have called the thlaspi, or treacle mustard.

*SINAPISIS*, a word used by some writers as a name for Armenian bole.

*SINAPISM*, *σινάπισμος*, formed from *sinapi*, or *σινάπι*, *mustard-seed*, in *Pharmacy*, an external medicine, in form of a cataplasm. See *SINAPIS*.

*SINAPISTRUM*, in *Botany*, Tourn. Infl. 231. t. 116, a name of Hermann's, alluding to the resemblance of the plant, or at least of its pods, to *Sinapis*, or Mustard. See *CLEOME*.

*SINARA*, the name of the male dancers, who, according to the mythology of the Hindoos, amuse their god Indra, regent of the firmament. (See *INDRA*.) These are perhaps the same beings whose name is sometimes written Cinnara, and described to be human figures with the head of a horse, but we never saw them so represented. See *SITANTA* and *SURA*.

*SINARUM REGIO*, in *Ancient Geography*, a country of Asia, and the last on the eastern coast, according to Ptolemy.

*SINARUS*, a river of India, which discharges itself into the Hydaspes, according to Arrian.

*SINASBARIUM*, in *Botany*, a name given by some authors to the silybrium, or water-mint, common in all our ditches and watery places.

*SINASSE*, in *Geography*, a town of Abyssinia; 40 miles N.E. of Miné.

*SINAY*, a small island near the W. coast of the island of Luçon. N. lat. 18° 11'. E. long. 120° 36'.

*SINBACH*, or *SIMPACH*, a town of Bavaria; 5 miles S. of Landau.

*SINCAPOURA*, or *SINCAPURA*, an island, with a town of the same name, near the S. coast of Malacca, which gives name to the narrow sea, called the "Straits of Sinca-poura." N. lat. 1° 12'. E. long. 103° 30'.

*SIN-CARPOU*, a town of Chinese Tartary; 555 miles E.N.E. of Peking. N. lat. 41° 23'. E. long. 126° 46'.

*SINCERITY*, in *Ethics*, is that excellent habitude and temper of mind, which gives to virtue its reality, and makes it to be what it appears. *Simplicity*, called by the Greeks *απλοτης*, is included in this virtue, but does not express the whole of it; so that it is necessary to add *αληθεια*, *truth*: of which two the first stands in opposition to what is mixed and adulterated; the other to what is counterfeit. *Sincerity* has respect to two sorts of objects; persons and things. Of the first kind are God; other men, and every man's self. Sincerity, with regard to God, signifies, that the form of religion is accompanied with the power of it, and that piety and obedience are substantial and unaffected; proceeding from principles, right in themselves, and uniform in their influence. Sincerity, as it regards men, implies an honesty

and openness in our dealings with them, extending to the springs and motions of our actions, as well as the actions themselves; to our words and our thoughts. Sincerity, with relation to a man's self, is opposed to self-deception. As to things, truth and goodness are the principal objects of sincerity. The extremes of this virtue are over-frankness and hypocrisy. Grove's *System of Moral Philosophy*, vol. ii. ch. 3.

SINCHO, or CHINCO, in *Geography*, a town of Africa, in the kingdom of Ningo, on the Gold Coast, the inhabitants of which are chiefly employed in fishing.

SINCIPUT, in *Anatomy*, the fore-part of the head, in opposition to occiput.

SINCKEL, in *Geography*, a river of Bavaria, which joins the Wertha; 2 miles S.S.W. of Augsburg.

SINCLAIR. See ST. CLAIR.

SIND, in *Agriculture*, provincially to rinse or wash out, as a milking pail, dish, &c.

SINDA, in *Ancient Geography*, a town of India, on the other side of the Ganges, placed by Steph. Byz. on the coast of the great gulf between Corgatha and Pagrafa.—Also, a town of Asia, in Pifidia, on the confines of Caria. Strabo.—Also, a town of Asiatic Sarmatia, upon the Cimmerian Bosphorus, between the ports Sindicus and Bara, according to Ptolemy.

SINDA, in *Geography*, a town of Hindoostan, in Baglana; 20 miles N.W. of Naffuck.

SINDÆ, in *Ancient Geography*, the name of three islands in the Indian sea, S. of the Baruffæ, according to Ptolemy.

SINDAGUA, in *Geography*, a ridge of mountains in South America, between Popayan and the Pacific ocean.

SINDANGAN BAY, a bay on the N.W. coast of Mindanao, extending from N. to S. about 100 miles. N. lat.  $8^{\circ} 15'$ . E. long.  $123^{\circ} 5'$ .

SINDE. See INDUS.—Also, a river of Hindoostan, which rises about 20 miles W. of Bilfah, and runs into the Jumnah, at Putterahee.

SINDEJUA, a town of Napaul; 40 miles W. of Moampour.

SINDELINGEN, a town of Wurtemberg; 6 miles S.W. of Stuttgart. N. lat.  $48^{\circ} 41'$ . E. long.  $8^{\circ} 52'$ .

SINDER, a town of Hindoostan, in Baglana; 15 miles S.E. of Naffuck.

SINDERINGEN, a town of Germany, in the county of Hohenlohe, on the Koher; 12 miles N.E. of Heilbron. N. lat.  $49^{\circ} 16'$ . E. long.  $9^{\circ} 33'$ .

SINDESSUS, in *Ancient Geography*, a town of Asia Minor, in Caria. Steph. Byz.

SINDI, a people of Asiatic Sarmatia, in the number of those who inhabited the Cimmerian Bosphorus. Strabo.

SINDIA, a town of Asia Minor, in Lycia. Steph. Byz.

SINDIANI, a Scythian people who inhabited the vicinity of the Palus Mæotis, according to Lucian.

SINDICUS PORTUS, a part of Asiatic Sarmatia, on the coast of the Cimmerian Bosphorus, according to the Periplus of Scylax.

SINDINICES, a people of Germany, who formed a part of the nation of the Vandals.

SINDION, in *Geography*, a town of Egypt, on the W. branch of the Nile; 14 miles S.S.E. of Rosetta.

SINDITE, in *Ancient Geography*, a town of Lesser Armenia, in the prefecture of Mauriana. Ptolemy.

SINDKEERA, in *Geography*, a town of Hindoostan, in the circle of Naderbar; 15 miles W. of Tolnani.

SINDOCANDA, in *Ancient Geography*, a town placed by Ptolemy on the W. coast of the isle of Taprobana, between the mouth of the river Soana and the port Priapius.

SINDOLE, in *Geography*, a town of Hindoostan, in Orissa; 15 miles N. of Sonepour.

SINDOMANA, in *Ancient Geography*, a town of India, and the capital of the territories of Muficanus. Arrian.

SINDON, in *Scripture History*, a word properly signifying a shroud, and used by the evangelists to denote the linen cloth in which Joseph of Arimathea wrapped the body of Jesus, after its embalment, &c. (Matth. xxvii. 59. Mark, xv. 46. Luke, xxiii. 53. John, xx. 7.) Sindon is also mentioned in the history of Samson. (Judges, xiv. 12, 13.) The virtuous woman mentioned by Solomon (Prov. xxxi. 24.) made findons and girdles, which she sold to the Phœnicians. The young women of Jerusalem wore findons. (See If. iii. 23.) This was a fashion peculiar to the Sidonians and the Phœnicians, and perhaps the name was derived from the city of Sidon. Martial says, that the findon of Tyre, or Phœnicia, covers a man all over, and puts him in a condition to despise rain and wind.

“ Ridebis ventos, hoc munere tectus, et imbres

Nec sic in Syria Sindone tectus eris.” Mart. l. iv. ep. 19.

The young man who followed Jesus Christ on the night of his passion, “ amictus findone super nudo,” was probably thus defended against the cold, as by a night-gown. Mark, xiv. 51.

SINDON, in *Surgery*, a little round piece of linen, or silk, or lint, used in dressing the wound after trepanning. The first thing usually done after the operation of trepanning is, to pour a few drops of white balsam on the dura mater; then a spoonful of mel rosatum being warmed with a little balsam, a findon is dipped into it, of fine linen cloth: this is immediately applied upon the dura mater; and being greater than the hole in the skull, its circumference is thrust all round between the cranium and the membrane; then pledgets of lint are applied, and the hole is quite stopped with it. The next morning, when the dressing is taken off, the brain is never left bare a moment; but as soon as the former findon and lint are removed, new ones are clapped on in their room.

SINDOS, in *Ancient Geography*, a town of Mygdonia, a country of Macedonia, W. of Therma, between this town and the mouth of the Axios. It is called by Steph. Byz. Sinthos.

SINDOURCOTTY, in *Geography*, a town of Thibet, on the left bank of the Ganges; 48 miles S. of Gangotri.

SINDRY, a town of Bengal; 45 miles S.E. of Nattore.

SINDSCAR, or SINJA, a town of Asiatic Turkey, in the government of Mosul; 30 miles S. of Mosul.

SINDY. See SCIND.
